We shall not attempt to describe a public and general *auto-da-fe*, because all the circumstances attending that ceremony may be found detailed in several works, and even represented in engravings, which exhibit to the eye a picture of the horrors of which no pen can convey any adequate conception. We shall only speak here of the *san-benito*, to which reference has already been made in a previous part of this article.

This vestment was merely a kind of scapulary which was fitted close to the person, and descended only to the knees, in order that it might not be confounded with any form of the monastic habit. This last circumstance led the inquisitors to perfer for the *san-benito* an ordinary woollen stuff dyed yellow, with crosses of a red colour, by which means every trace of resemblance between the habit in which the penitents of the Inquisition were clothed, and that worn by any of the religious orders, was completely annihilated. Such was the *san-benito* in 1514, when Cardinal Ximenes de Cisneros caused the ordinary cross to be replaced by that of St Andrew. Afterwards, however, the inquisitors varied the forms of the *san-benito*, in order that one of these might be applicable to each class or description of penitents. But we shall only mention here those which were in common use.

When a person had been declared *slightly suspected* of heresy, and condemned to make abjuration, if he demanded to be relieved from the censures *ad cautelam*, he was made to assume a *san-benito*, which the Spaniards of the fifteenth century called *zamarra*, and which was merely the scapulary we have already mentioned, without a cross in saltier. But if the condemned abjured as one *violently suspected*, he bore one-half of this cross; and if he made abjuration as a *formal heretic*, he bore it entire. This, however, applied only to those who, after having been reconciled, had their lives spared. But there were other kinds of *san-benito* for those who were condemned to perish in the flames. He who, after having been once absolved from the crime of formal heresy, and reconciled to the church, relapsed into his former errors, was denominated *relapsed*, and incurred the pain of death. His fate was inevitable, however lively might be his repentance, and even notwithstanding a second reconciliation. The only advantage which this last act procured him, was that of not being burned alive. He was merely strangled, or put to death in some other manner less horrible than by fire, and then his corpse was delivered to the flames. Thus, as there were three kinds of *san-benito* for the three classes of condemned who were delivered to the secular arm, so also the inquisitors contrived an equal number for those who were doomed to suffer death.

The *first* was that of prisoners who had repented before being condemned. It was formed of a simple yellow scapulary, with an entire red cross in saltier, and a round pyramidal bonnet, called *coroza*, of the same stuff as the *san-benito*, and garnished with similar crosses, but without any representation of flames, because the repentance of the accused having been manifested in time, had saved them from the penalty of cremation. The *second* was destined for those who had been definitively condemned to be delivered to secular justice, in order to undergo the pains of fire and who had repented, after their condemnation, and before being conducted to the *auto-da-fe*. The *san-benito* and the *coroza* were made of the same stuff. On the lower part of the scapulary was represented a human bust on a brazier, whilst the rest of it was covered with the resemblance of flames pointing downwards, to indicate that the criminal was not to be burned alive, because he had not been adjudged to suffer that punishment, but only to be thrown into the flames after being strangled. The same representations were painted upon the *coroza*. The *third* was for those who were treated as guilty of final impenitence. It was made of the same stuff (serge) as the others. The lower part exhibited a human bust on a brasier, surrounded with flames; and the rest was covered with flames in their natural direction, to shew that he who wore it was doomed to actual burning. On the vestment were also delineated grotesque figures of devils, which were painted thereon, to indicate that these lying spirits had entered and taken up their abode in the soul of the guilty. The *coroza* was charged with similar figures. Such were the principal forms of the *san-benito*. The others were intended for those adjudged to suffer milder penalties, as confinement and penance, and generally had inscribed on them the name, country, species of heresy, punishment, and date of condemnation of the delinquent, accompanied with a cross in saltier or with flames, according to circumstances.

As the Inquisition was the creation of an intolerant age, when religious zeal was envenomed by bigotry, and exasperated by schisms and divisions, so it has fallen before the humanizing influence of modern civilization, and is now, even in Catholic countries, only a matter of history. In Spain and Portugal it has ceased to exist even in name; in Italy and other countries, where it has not been formally abolished, it is merely an obsolete institution, which henceforward no one will ever succeed in reviving. But the time was when it acted with fearful energy and efficacy, and when, like the Vehmgericht of the middle ages, it struck terror into all hearts. In Spain alone, according to Llorente, upwards of three hundred and forty thousand persons were judged and punished, one way or other, by this tribunal. The following is the general result of his statement in figures:—

Burned alive,	31,912
Burned in effigy,	17,659
Subjected to rigorous pains and penances,	291,450
Total,	341,021

And if to the number of victims immolated by the Inquisition in the Peninsula, be added all the unfortunates who were condemned by the tribunals in Mexico, Lima, Carthagena, Sicily, Sardinia, Oran, Malta, together with Naples, Milan, and Flanders, whilst these countries were under the dominion of Spain, it would probably be found that more than half a million of human beings had been condemned by this inexorable tribunal to undergo various punishments, a large proportion of which inferred infamy. (A.)

INSCRIBED, in *Geometry*. A figure is said to be inscribed in another, when all its angles touch the sides or planes of the other figure.

INSCRIPTION, in Latin *Inscriptio* (a word formed from the preposition *in* and *scribere* to write), and signifying something written or engraved on any substance, whether of wood, stone, metal, or other material, and having for its object to transmit to posterity the record of some important event or transaction.

It is well known that the ancients engraved on temples and columns the principles of science, as well as the events of history. In the early ages of the world this was the only means by which valuable truths could be preserved, and the memory of important transactions transmitted to succeeding ages. Sanchoniathon, a Phœnician historian, born at Berytus in Syria, and who flourished about the time of the Trojan war, is said to have drawn most of the materials of his history from inscriptions which he found in temples and on columns, both in his own country and in Palestine. But however this may have been, the circumstances mentioned by Herodotus shew, that the first method of instructing men, and of transmitting sciences as well as history to posterity, was by inscriptions. And this is confirmed by Plato, who, in his *Hippias*, informs us that Pisistratus caused to be engraved on stone, for the benefit of his countrymen, useful precepts in husbandry. Pliny assures us that the earliest public monuments consisted of plates of lead, on which were engraved the records of public transactions; and, in corroboration of this, he mentions, by way of exception, that the treaty of confederacy concluded between the Romans and the Jews, was inscribed on plates of brass, in order that the record of the compact might be less liable to be effaced, and that the Jewish people might always have something to remind them of the alliance which they had formed with the Romans. Nor were inscriptions discontinued in proportion as the art of writing was improved and facilitated. On the contrary, amongst the Greeks and Romans especially, this method of preserving the memory of important events, in connexion with distinguished names, continued to be employed long after it had ceased to be a matter of necessity; and hence the multitude of inscriptions, or fragments of inscriptions, which has outlasted the injuries of time, and the still more destructive dilapidations of barbarism.

Inscriptions are of different kinds, and they have been variously classed. Spohn, for instance, has divided archæography into no less than eight parts, viz. numismatography, epigrammatography, architectonography, iconography, glyptography, toreumatography, bibliography, and angiography. But this classification, which Boeckh has denominated rude, appears to be extremely unscientific and arbitrary, and not being founded upon any clear or definite principle, it is calculated to involve the subject in inextricable perplexity. A more natural and obvious division readily suggests itself. Inscriptions, generally considered, may be arranged in two classes, namely, *numismatic* and *monumental;* the former including the legends preserved on ancient coins and medals; the latter, the texts engraved on palaces, temples, and other edifices, together with those on columns, obelisks, statues, and such like monuments. The one of these branches is entirely distinct from, and can never be confounded with the other. In numismatics, our attention is exclusively confined to simple legends, consisting merely of names, titles, and dates. In monumental inscriptions we meet with texts, or the remains of texts, which, besides names and titular or official designations, contain, in a more or less perfect form, records of particular transactions or events, the memory of which it was intended thus to perpetuate. But the latter, with reference to their subjects, may nevertheless be subdivided into four different kinds. These are, first, the inscriptions relating to public affairs and civil institutions, which it is the principal object of the historian to investigate; secondly, those which respect private affairs, or the economy and intercourse of common life; thirdly, those which relate to the ceremonies of religion, and the arts or observances therewith connected; and, lastly, those which have reference to the history of science, whether as respects philosophy, mythology, or any other branch of knowledge. Under one or other of these heads may be included every kind of monumental inscription.

The most remarkable inscriptions in the world are those sculptured on the temples, palaces and obelisks, or painted on the interior of the *hypogæa* or burial-vaults of the ancient Egyptians; the texts, in cuneiform characters, observed on the ruins of Persepolis, as well as on vitrified bricks found amidst the ruins of Babylon; and those preserved on the pillars and ornamental parts of the rock-temples of Elephanta, Ellora, Carli, and other ancient monuments in India. Of the first of these, some account has already been given in the article HIEROGLYPHICS, to which the reader is accordingly referred. In this interesting field of inquiry, modern sagacity has, in part, triumphed over the difficulties, so numerous and formidable, which seemed destined to oppose an insuperable barrier to all investigation. But much, very much, yet remains to be done; indeed, the task may be said to have only been commenced. Proper names have been deciphered, legends have been interpreted and explained, dates have also been determined; but the body of those texts, to which the history of ancient Egypt has probably been consigned, still remains as great a mystery as ever. To a double or perhaps triple lock only one key has as yet been found. With regard to the Persepolitan characters, again, various attempts have been made to decipher them, though hitherto without any certain or assignable success. By a fortunate accident or rather conjecture, M. Saint-Martin has, we understand, been enabled to detect the name of *Xerxes* upon a vase in the cabinet of the King at Paris. But whilst little reliance can be placed on such divinations, it is plain that the interpretation, even if well-founded, cannot afford sufficient data for advancing a single step beyond it. No parasite translations into any known language have been discovered, as in Egypt, where the pillar of Rosetta and the monument of Philæ afforded the means of instituting tentative comparisons, and furnished the elements of an alphabet; nor is it at all probable that, without some such accessory helps, any progress will ever be made in determining the values of the nail-headed characters. The Indian inscriptions, also, still remain in a great measure undeciphered; nor has there yet been found any certain or safe clew calculated to lead to the interpretation of the characters in which they are written, much less of the texts which these characters have been employed to express. The discovery of such a key, indeed, is a question in the theory of probabilities, where the chance of failure is to that of success, within a given time, as a number incalculably great to unity. Some interpretations have, indeed, been published, as for example of the Allahabad and Delhi inscriptions, and also of those found in the caves of Carli; but none of the interpreters, so far as we know, has condescended to state the data on which he proceeded, or to explain the process by which he was enabled to construct an alphabet; and it must be evident that, without the most distinct and precise information on this point, no confidence can be placed in the results alleged to have been obtained.[1]

Inscriptions in an unknown character have also been found cut upon granite and sandstone rocks, between Mount Sinai and the Red Sea. Several specimens of these now lie before us, copied from the rocks at Wady Magara, Gebel Mokat'teb, Mount Horeb, Wady Maggup, and Nasby. With the exception of a mixed inscription, and also one in Greek, and another Cufic, they are all in the same character. In those found at Wady Magara and Gebel Mokat'teb, we discover rude delineations of the camel, the horse, the goat, and the antelope, with, in one instance, the figure of a man holding a club or staff in his hand. The characters bear a considerable analogy to the Cufic, though much more distinct; and, judging from the figures of loaded camels, with their heads all turned in the same direction, it seems not improbable, that the texts record the transits of different caravans. In one of these inscriptions, a number of characters are marked out in such a manner, by a line underneath, as to suggest the idea that they represent the name of some distinguished person, upon a principle analogous to that which was observed in the royal scrolls of the Egyptian writing; and this conjecture is somewhat countenanced by the circumstance that, amongst the characters thus defined, there is one which occurs thrice. But there exist no data upon which to found an attempt at interpretation; nor can any opinion be formed as to their relative antiquity.

In the countries of the west, where civilization is comparatively but of recent origin, few remains of extinct forms of writing have been discovered. This is easily accounted for, because, in Europe, the origin of letters is of much more recent date than in those countries where such interesting relics are found. The language of the Eugubian tables is, no doubt, an exception, inasmuch as all the learning and ingenuity of scholars have as yet been insufficient to analyze its structure, or to penetrate the meaning of the texts in which it has been partially preserved. But, by a singular anomaly, the characters on these tables have been resolved into an alphabet; and it may not unreasonably be hoped, that the power thus obtained of combining words, will ultimately lead to the discovery of their respective values. The Runic characters and the Runic language are now pretty well understood.

But the category of inscriptions to which the most direct interest and the greatest importance are naturally attached, whether with reference to the subjects of history, antiquities, or philology, is that which includes the monumental remains of Greece and Rome, particularly of the former.

Not to mention the writers who, between the age of Herodotus and that of Cosmas Indopleustes, or even later, make frequent mention of inscriptions, Philochorus of Athens, who flourished between the 118th and the 129th Olympiad, and was deeply skilled in Attic antiquities, appears to have been the first who applied himself to this subject; and, on the authority of Suidas we learn that he published Ἐπιγραμματα Ἀττικα, or Attic inscriptions of different kinds. He was succeeded by Polemo Græcanicus, the son of Euegetus, and the contemporary of Aristophanes of Byzantium, who, on account of his indefatigable study of inscriptions, was denominated Στηλοκοπας. His principal works on this subject were, first, περι των κατα πολεις ἐπιγραμματων; secondly, περι των ἐν Λακεδαιμονι ἀναθηματων; thirdly, four books περι της Αθηνησιν ἀκροπολεως; and, lastly, περι των ἀναθηματων ἐν τη ἀκροπολει. Mention is also made of a book περι των Θηβαϊκων ἐπιγραμματων, by Aristodemus, a writer on Theban affairs, whose works have utterly perished. To these succeeded Alcetas περι των ἐν Δελφοις ἀναθηματων, Menetor περι ἀναθηματων, Apellas Ponticus, and Neoptolemus Parianus περι ἐπιγραμματων, who were afterwards followed by the authors of the Anthologies. Of the collections of Philochorus, Polemo, and others, however, nothing remains excepting some expressions, such as σταθμια χαλκᾶ and κερας ἐκπωμα ἀργυροῦν, with a few others; but it appears that, anciently, there existed a repository or collection of confiscated goods, arranged according to a method copied from the inscriptions, and that this fact was known both to Athenæus and to Pollux. The book of Heliodorus, περι των ἐν Αθηνησι τριποδων, must also have embraced inscriptions, as we find that the ancients early employed the denomi-

[1] With regard to the Carli inscriptions, the Rev. Mr Stevenson of Poonah, having directed his attention to the subject, employed a year and a half in searching for a key amongst the natives; but as the latter were wholly unacquainted with the characters in which these inscriptions were written, his researches proved fruitless. He then made a collection of alphabets used on the western side of India, and attempted, by means of these, to decipher the inscriptions; but still with indifferent success. The publication of the Allahabad inscription, however, gave a new impulse and direction to his studies, and at length he was enabled, though we are not informed how, to read and translate the Carli inscriptions. It would certainly have been much more satisfactory, and, in appearance at least, far less empirical, had Mr Stevenson condescended to state the data on which his method of interpretation is founded.

But be this as it may, the results alleged to have been obtained from the Carli inscriptions deciphered are curious. These are, first, that the rock temple in question was excavated about sixteen centuries ago; secondly, that the empire of Shalivahana, in the Deccan, continued at least a hundred years after his time; thirdly, that Buddhism was the religion at that time favoured by the ruling party; fourthly, that the Shakas, so far from supplanting the language and literature of the Brahmins, adopted the Sanscrit as the vehicle for transmitting the memory of their own deeds to posterity; fifthly, that a simpler character than the Devanagari was probably used at the time when the Vedas and other ancient compositions were committed to writing; sixthly, that the Arabic numeral ciphers had been introduced into India at the period above mentioned; and, lastly, that great caution must be observed in admitting local traditions as of authority in regard to the condition of society or the state of knowledge and manners in such remote times.

These results, however, though probable enough, require confirmation. We have already observed that Mr Stevenson's scheme of an alphabet is not satisfactorily developed; and Mr Princep found that, when applied to the Allahabad inscription, it did not convert the text of that monument into intelligible Sanscrit. Besides, Mr Hodgson, resident in Nepaul, has expressed his conviction that the characters of this incription, so far from having preceded, are in fact derived from the Devanagari, or literal symbols of the learned Hindus. It appears, also, that the Allahabad and Delhi inscriptions are identical with one discovered at Mattia-lath, on the Nepaul frontier.

nation of tripod. Lastly, Craterus Macedo, whom Niebuhr considers to have been the brother of Antigonus Gonatas, son of Craterus and Phila, published Ψηφισματων συναγωγην, or books περι ψηφισματων, in which he sought to confirm public transactions by extracts of decrees and other documents, the greater part of which he, doubtless, derived from inscriptions, whilst as to the remainder, it was in all probability obtained from the Attic rolls or registers. From this collection of Craterus, indeed, and from others of a similar description, derived from the same sources, those who have preserved to us the Attic decrees copied the documents which we find embodied in their works; and to it also may be referred the greater part of the decrees inserted by the orators, particularly those cited by Demosthenes in his celebrated oration for the crown.

The first modern work on inscriptions was that of Cyriacus Anconitanus, who, in the early part of the fifteenth century, applied himself to collect those remains which had escaped the ravages of the barbarous ages, and who, whatever some critics may allege to the contrary, displayed equal diligence and fidelity in the execution of this laborious undertaking. He was succeeded, at intervals, by a long series of learned men, extending downwards even to our own time, who devoted their talents and industry to the collecting, interpreting, and illustrating of the monumental remains of antiquity. Amongst these a distinguished place must be assigned to Gruter, whose *Corpus Inscriptionum* (Heidelberg, 1601, in folio) is still a work of high importance. It is an immense collection of Greek and Latin inscriptions, which having been commenced by Smetius, was considerably augmented by Gruter, who subjoined to it the *Notæ Romanorum veterum Tulii Tironis et Annæi Senecæ*, a work which has since been much surpassed. Gruter was followed by Reinesius, who compiled another large volume of inscriptions; and Reinesius was succeeded by Fabretti, who also published at Rome, in 1609, a large volume, in which he corrected numerous errors that had escaped preceding antiquarians, and added a number of inscriptions which they had omitted. The next collection which appeared was that of Grævius, in three volumes folio; a work of extensive erudition, and, in all respects, more complete than any which had preceded it. In the course of the last century, Scipio Maffei, a man of various learning, and eminently skilled in this branch of archæology, undertook to make a more complete collection than had yet appeared of Greek and Roman inscriptions, the former of which he proposed to include in the first volume of his work; but after the expenditure of much labour and research, he found that the enterprise exceeded in magnitude his powers of execution, and at length, in his old age, abandoned it in despair. The project of Carcanius, who meditated an universal collection of inscriptions, proved equally abortive; as did also that of Raponus, a man who, by his knowledge of Greek, was not unequal to the task, though he published only one commentation on Greek inscriptions, written in indifferent Latin. The first volume of Boeckh's splendid work, entitled *Corpus Inscriptionum Græcarum*, in folio, was published at Berlin in 1828, and at once established the author's claim to rank in the very first class of scholars and critics. It is indeed a masterpiece of learning, research, critical sagacity, and philosophical acuteness; nor, in point of typographical elegance and accuracy, is it equalled, or perhaps even approached, by any work which has yet appeared on the subject. This volume is divided into six parts, which treat respectively, of, 1. *Tituli antiquissima Scripturæ forma insigniores*; 2. *Inscriptiones Atticæ*; 3. *Inscriptiones Megaricæ*; 4. *Inscriptiones Peloponnesiacæ*; 5. *Inscriptiones Bœoticæ*; and, 6. *Inscriptiones Phocicæ, Locreæ, Thessalicæ.* Of the second volume only a small portion has as yet been published. Boeckh has drawn his materials not only from the larger collections of Gruter, Reinesius, Spohn, Fabretti, Muratori, Donius, Donatus, and others, but also from diaries, catalogues and descriptions of museums, itineraries, in a word, from books of every kind; and he acknowledges having been aided in his inquiries at the commencement of his undertaking by Bekker, Buttmann, Niebuhr, and Schleiermacher, as well as by Gerhard, Klütze, Müller, Bischoff, Steinhart, and other young men who have since distinguished themselves by their erudition. For full information as to the nature and object of the work, the method of treating the subject, the art of interpreting and emending inscriptions, examples of the most difficult and obscure fragments, and how the genuine are to be distinguished from the spurious, the entire from the corrupted or interpolated, the reader is referred to the general preface, which is full of curious and original learning.

Those persons who desire to study the Roman inscriptions, may consult any of the large collections already referred to; and they will also do well to bestow a careful perusal on Funccius *de Origine, Pueritia, et Adolescentia Linguæ Latinæ* (Francfort, 1720, in small 4to), a work of great learning, ingenuity, and research, in which the progress of the Latin language from infancy to maturity is distinctly traced, and appropriately illustrated. This magnificent idiom, which was gradually formed and perfected by grafting on the rude original stock of an uncouth and barbarous dialect successive improvements, suggested by converse with a refined people, who had made considerable advances in civilization, whilst Rome remained in a state of comparative barbarism, and which derived nearly all its peculiar excellences of form, structure, and expression, from the transfusion, partly of the vocabulary, and partly of the spirit of the ancient Greek, presents altogether one of the most interesting subjects of inquiry in the annals of philology; and it is chiefly by the aid of inscriptions that such an investigation can be successfully prosecuted. The history of the language, in short, reflects, like a glass, that of the progress of social and intellectual improvement. With regard to ancient Roman numismatics, the best manual, perhaps, which has yet appeared on the subject, is the work of M. Hennin (Paris, 1830, in two vols. 8vo), containing the elements of the science, and the nomenclatures, with an indication of the degrees of rarity of the antique monies and medals, and tables of their actual values. The first volume treats of the origin of monies, an invention which followed the introduction of commerce by exchange; of the epochs distinguishable in the style of the art, the legend, the form of the characters, and the metal employed in the coins; of the titles and functions of the persons entrusted with the direction of the fabrication of coins; of the materials employed in ancient coins and medals, their names, values, weights, dimensions, inscriptions or legends, and dies, with the method of detecting spurious medals; and, lastly, of the history of numismatical science. The second volume is occupied with four nomenclatures, which comprehend the whole of numismatics. The first is that of peoples, cities, and kings, arranged in the geographical order adopted in the cabinets; the second is that of the Roman *as*; the third is that of the medals of Roman families; and the fourth is that of the Roman emperors, of the Cæsars and the Tyrants, classed in chronological order. Each nomenclature is accompanied with a table of the value of the medals, which, however, is not remarkable for its accuracy. The works of Jobert, Patin, and Mangeart, though they contain excellent things, are antiquated; the Introduction of Millin, the Summary of Champollion-Figeac in the Portable Encyclopædia, and the Essay on the science of Medals by Dumersan, in the Numismatics of Anacharsis, are merely abridgments, which can scarcely satisfy those who desire to make themselves thoroughly masters of the subject.

As to the study of inscriptions, little need be said to shew its indispensable importance to the historian and philosopher, as well as to the antiquary and philologist. The records thus preserved contain much information which is not to be found in ancient authors; and they afford the best tests by which the accuracy of historians may be tried, their fidelity proved or impeached, their errors corrected, and their defects supplied. They determine dates, establish facts, and throw light on the modes and habits of civil life, as well as the observances of religion; whilst in many of them the most important historical documents have been preserved. In fact, it is only necessary to consult the Roman History of Niebuhr, to be satisfied as to the importance of inscriptions, considered as materials of history, and how greatly they may contribute, when skilfully interpreted and rightly understood, to elucidate obscurities, dispel doubts, correct mistakes, and reduce to their true value the fabulous legends of romancing chroniclers and poetical historians. Again, it is in inscriptions that the various phases, changes, and transitions of language are reflected as in a glass; it is by means of them alone that we are enabled to trace the progressive steps by which it advanced from its primitive state, characterized by a rude simplicity, to the more refined, perfect, and complicated form which, by a course of gradual improvement, it afterwards attained. The text of the Duilian column, for example, is an invaluable monument to the historian of the Latin language, which it exhibits in a state of transition from the rugged and uncouth form of a barbarous and dissonant dialect, such as that of the *Carmen Saliare* and the Fescennine verses, to the finished regularity of structure, and philosophical precision and elegance of arrangement, which we discover in the great writers of after times. As to the learned antiquary, again, he lives, moves, and has his being amidst these interesting monuments of the past; and whilst pursuing his minute investigations, perchance contributes in no unimportant degree to throw a new light on facts of more pith and moment than any of those which more immediately engage his attention. In a word, we may say to the historian, the scholar, and the antiquary, in regard to inscriptions, *Nocturna versate manu, versate diurna.* (A.)

INSCRUTABLE, Unsearchable, in *Theology*, is usually understood of the secrets of Providence, and the judgments of God, into which human reason is unable to penetrate.

INSECTS, Insecta, in *Natural History*. See Entomology.

Noxious Insects; Means of destroying them, or preventing their increase. Of those substances which have been generally observed to be efficacious in driving away or in destroying insects, mercury, and its various preparations, may be reckoned the most generally effectual. Sulphur is also useful. Oils of all kinds have often been deservedly recommended; and tobacco is not less remarkable for its utility.

Mercury is known to kill or drive away lice from the human body; and it may probably be of equal efficacy in ridding other animals of insects. For instance, a small quantity of mercurial ointment rubbed upon the skins of sheep, on the sides, between the fore-legs and the body, may kill or drive away the insect peculiar to these animals. Sulphur is recommended to be added to the mercurial ointment. Thus not only the insect peculiar to them, but also the scab, may be cured.[1] Ailway[2] directed that, in the winter, the walls, frames, and other parts of his green and hot houses should be well washed with corrosive sublimate mercury, dissolved in water. These houses had been greatly infested with red spiders and ants. After having been washed with this solution, neither of these were to be seen next summer. This wash, if made weaker, may be used on old garden-walls, and the roots of fruit-trees infested with insects. It may destroy the tender leaves of plants, though not the roots. The same wash will effectually destroy that disagreeable insect the bug, and all other insects of a tender cuticle; and it will not in the least hurt the colour of bed-furniture or hangings. Care must be taken that the wash be applied into every crevice or folding of the furniture with a painter's brush. It will sometimes be necessary to repeat the wash, as the ova of bugs may remain concealed, notwithstanding the utmost care.

Some of the West India islands were much infested with large ants, which greatly injured the sugar-canes. The remedy was, to dissolve corrosive sublimate mercury in rum, in the proportion of two drams to a pint of spirits. This solution was poured upon dry powdered sugar; and when the sugar was dried, it was laid in the paths of the ants. They ate it, and were destroyed. Might not this practice be imitated, by laying sugar thus prepared on paper or pieces of thin boards near the roots of fruit-trees infested by insects, especially when the fruit is ripening? The papers or boards might be taken in during the night, or when it rained. The sugar should be coloured with indigo, or other substance, thereby to mark it as a substance to be avoided by curious idlers.

We are informed that a person in Philadelphia employed brimstone in the following manner. Having cleared all round the roots of trees infested with caterpillars or other insects, he strewed some flowers of brimstone round the roots, and covered it with a thin sprinkling of fine mould, that it might not be blown away by the wind, yet so that the sun might operate through the mould, and cause the brimstone to fumigate. In this manner he destroyed the caterpillars. One pound he found sufficient for two hundred trees. In that hot climate the sun may perhaps have that effect; but it scarcely will in this. To drive insects from small trees, he also employed sulphur in the following manner. He split the end of a pole, and put in the slit some matches, set them on fire, and held them under the parts of the trees chiefly affected. A pole thus armed, he found, would answer for three or four trees. Brimstone mixed with damp straw, and set on fire, in hop-ground infested with the fly, for instance, might be of use in driving away that insect.

The itch is supposed to originate from a very small insect which nestles under the skin, and proceeds no farther; and it is, therefore, attended with no dangerous consequences. Brimstone made into an ointment with hogs-lard is a sure remedy.

Sheep are liable to an eruption on the skin, known by the name of the *scab*. Brimstone, when added to the mercurial ointment recommended for that disorder,[3] might perhaps render the application more efficacious and less dangerous.

The natives of hot countries are taught by experience, that an unctuous covering of their bodies prevents the bites of musquitos and all gnats. The white inhabitants in such countries are not sufficiently careful in preventing the least stagnant water near their dwellings, in which the musquitos are bred; they are produced even in the waste water thrown out. Dr Franklin, by a careful attention to this circumstance, guarded his family in Philadelphia from such insects. One day seeing a number of musquitos in his library, he found on inquiry, that one of his servants had taken off the cover of a tub placed near his window for receiving rain-water. On such an occasion the remedy is

[1] *Transactions of the Society for the Encouragement of Arts*, London, vol. vii. viii. p. 90.
[2] *Ibid.* vol. v. vi. p. 59.
[3] *Ibid.* vol. vii. p. 90.

easy, namely, shutting up the room for the day, so that the musquitos cannot come at any water, in which time they die. Though this caution may seem trifling to us who live in a mild climate, it is far otherwise in hot countries.

Oil being known to be most efficacious in destroying insects, may not the use of it be extended to the destruction of worms in the bowels of horses, where they probably occasion the violent pain which these animals seem sometimes to suffer? If the horse were for some time kept fasting, and a large quantity of oil, say a pint, were given, supposing worms were the cause, the oil might in that case destroy them.

Flowers, leaves, and fruits, are known to be devoured by caterpillars. But these are destroyed by oils, which close the lateral pores by which they breathe. For this purpose it is advised that, on the approach of spring, a cloth dipped in train oil be laid on those parts of the tree in which there is any appearance of them.

We are informed in the Memoirs of the Society of Agriculture at Paris, that oil of turpentine, when applied to animals covered with insects, destroyed the insects without hurting the animal. The author tried it on several trees, mixed with fine earth so as to incorporate therewith, adding water, till the whole was brought to some degree of fluidity. In this mixture he dipped branches of fruit-trees on which there were insects, and thereby destroyed not only the eggs but also the insects, without hurting the leaves. This composition may be got off by washing, or the first heavy shower. From these experiments the author thinks, that oil of turpentine may with equal efficacy be employed for killing various kinds of lice on domestic animals.

We are informed that Mr Winter, amongst other experiments on turnip-seed, steeped the seed twenty-four hours in a sufficient quantity of train-oil. He then drained the oil from the seed, which he mixed with a quantity of fine sifted earth, and immediately sowed it in drills. When the plants began to appear on the surface, the ground was sown with soot. He found that seed steeped in linseed oil answered equally well.[1] The turnips least injured by the fly, were those which grew from seed steeped in this way; they grew so luxuriantly as to produce rough leaves several days prior to the most flourishing of any of his other experiments, and were the better enabled to withstand the attack of the fly. The leaves of these turnips were of a darker green, and appeared twice as thick in bulk and luxuriancy as the other turnips, and were considerably larger. The seed was drilled an inch and a half deep, and a foot distant in the rows. Train oil is apt to kill the leaves of plants which have been injured by insects, but linseed oil has not that effect, though equally destructive to the insects. The train oil seems to act as an oil, and by its disagreeable smell to prevent insects approaching it. In this respect it may be successfully used to prevent field mice or other vermin preying on acorns, chestnuts, or other seeds steeped in it before they are sown.

When thus giving directions for preventing the fly on turnips, an experiment may be mentioned, by the disclosure of which a person gained a considerable reward. His secret was, running a roller over the ground early in the morning, whilst the dew remained on the ground, on the first appearance of the fly. The dew entangled the flies so much, that they could not make their escape, and were therefore crushed to death. But as the roller may leave the surface of the earth too hard, it was recommended to fix some boughs of elder in a gate or hurdle, to be drawn over the field; and if the boughs had before been fumigated with the smoke of tobacco, or tincture of assafœtida, the success would be the surer. The most certain method of preventing the injury done by the fly is to raise the plants in a nursery, and at a proper age to transplant them, being carried to the ground in a wheel-barrow filled with manure softened with water so as to admit the plants. This method will secure their more speedy growth. In the nursery the attack of the fly may be prevented by sprinkling soot or quicklime on the ground. The utility of transplanting turnips is evident by the practice of transplanting the turnip-rooted cabbage. They who are discouraged from having recourse to this practice by the expense attending it, do not reflect that the hoeing is prevented, and the plants grow the better, being set in fresh earth.

Before proceeding to direct the use of the last means mentioned, viz. tobacco, for destroying insects in turnips, it may be proper to mention an experiment made by Mr Green, of the flower-garden at Kew. He contrived a pair of bellows similar to that employed in recovering people apparently drowned. It had a cavity in the nozzle, in which some tobacco was put, with a live coal over it. The bellows being then worked, the tobacco was set on fire, and the smoke directed to any particular spot. A lady was fond of having the mosk-rose in her dressing-room, but was prevented having it on account of the green insects which constantly adhere to that plant. To remedy this inconvenience, Mr Green had a box made large enough to contain a pot in which a plant of the mosk-rose grew. In one end of the box was a hole, to admit the nozzle of the bellows; the bellows was worked, and the smoke was received into the box. When the tobacco was consumed, the nozzle was withdrawn, and a cork being put into the hole, the box thus remained till morning, when the insects were all laid dead on the earth. Being swept off, the plant was in a state fit for a dressing-room. Many plants thus infested with insects may be too large, or otherwise so placed as not to be put into a box. In this case it occurred to the writer of these observations, that sprinkling the plants with an infusion of tobacco in water might in some degree answer the same purpose. On trial he found it answer, and he thus freed other plants from their insects. He also used it on trees of easy access with advantage. Train oil is so inimical to tender plants or leaves, that it destroys them if insects have in the least hurt them; whereas the infusion, instead of killing the leaves, promoted a fresh vegetation.

Fruit-trees often become the prey of insects. Those trained against a wall, or as espaliers, being easily come at, much of the mischief may be prevented by cutting off the leaves as soon as they are observed to be curled; for then fresh eggs are laid on them, probably by butterflies. If sprinkled with the infusion of tobacco, it will prevent their coming to life. After the fruit is formed, the infusion must not be used, lest the taste and smell should remain. The scissors are then the proper remedies, which ladies may employ as amusement, and may thereby present fruit to their friends of their own preserving. A lye of the ash of plants sprinkled on the leaves may have a good effect, as also on other pot-herbs, which are often the prey of caterpillars. As many insects, besides those bred on the leaves or in the walls, may destroy the fruit, the sugar with the corrosive sublimate, as already described, may be laid in the way of other insects, to all which it will prove a speedy death. Diligent inspection of their retreats is the most certain means of preventing the loss sustained by snails. Ants are prevented rising up the trees by laying round the roots powdered chalk, or any other substance which, by entangling their feet, prevents their crossing it. Care should be taken to destroy their nests everywhere near the garden.

Hops have now become an article of so great consequence, that it deserves our particular attention. Early in its growth when the vines begin to ascend the poles, a black fly preys

[1] *Transactions of the Society for the Encouragement of Arts*, vol. v. p. 45.

on its leaves, frequently in such numbers as, by destroying the leaves, to interrupt the vegetation, much of the food of plants being absorbed by the leaves. The infusion of tobacco destroys them, or at least drives them away so effectually, that a plant almost totally stripped of its leaves has put out fresh leaves after the use of the infusion. If care be not taken, the insects will again fall on the fresh leaves. As the flies lodge on the lower side of the leaves, they are protected from storms of rain, and therefore the infusion must be driven upwards by a forcing-pump. It is said that the expense of tobacco is too great, but perhaps lime-water, or even water by itself, driven strongly against the leaves, might drive them away. The labour attending such experiments in a large plantation discourages persons, who do not reflect, that, if such means are used early, the flies may more easily be got rid of. Free ventilation is undoubtedly beneficial to all plants; and hence perhaps the particular advantages of drilling corns in rows a little distant. If alleys somewhat larger than common were made in the plantations of hops, there might be sufficient spaces left, where the alleys cross one another, to admit of setting damp straw or other materials mixed with brimstone, soot, or the like, on fire. Smoke itself is said to prevent the fly; and if so, it still will act more powerfully when mixed with such materials. It has been observed in Sweden, that the hops grow naturally amongst heaps of stones or fragments of rocks. They therefore advise to cover the ground round their roots with stones, which will prevent the insects laying their eggs near the roots in the ground, where they lay them to be protected during the winter. The stones will also preserve moisture at the roots during the summer. A rope cannot be drawn across a plantation of hops, as it can across a field of corn, in case of mildew. Here water to wash off the clammy juice, which entices and feeds insects, seems to be the only remedy. The plantation being well ventilated, may at least prevent the frequency of it. The forcing-pump will most effectually wash off this exudation.

INSINUATION, denotes a cunning and covert way of creeping into any person's favour; or it means something conveyed by implication or innuendo.

Insinuation *of a Will*, amongst civilians, is the first production of it, or the leaving it with the registrar, in order to its probate.

INSOLVENT, a term applied to such persons as have not wherewithal to pay their just debts. See Bankruptcy.

INSPECTOR, a person to whom the care and conduct of any work is committed.

Inspectors, in the Roman law, were such persons as examined the quality and value of lands and effects, in order to the adjusting of taxes and impositions in proportion to every man's estate.

The Jews have also an officer in their synagogue, whom they call חזן, *hhazen*, or *inspector*. His business consists principally in inspecting or overlooking the prayers and lessons, in preparing and shewing them to the reader, and in standing by him to see he reads correctly; and, if the latter make mistakes, he is to correct him.

INSPIRATION, amongst divines and others, implies the conveying of certain extraordinary and supernatural notices or intimations into the soul; or it denotes any supernatural influence exercised by God upon the mind of a rational creature, by which he is formed to a degree of intellectual improvement, to which he could not or would not have attained, in his present circumstances, in a natural way. Thus the prophets are said to have spoken by divine inspiration.

Some authors reduce the inspiration of the sacred writers to that particular care of Providence, which prevented any thing they had said from failing or coming to nought; maintaining, that these writers were not really inspired either with knowledge or expression.

According to M. Simon, inspiration is no more than a direction of the Holy Spirit, which never permitted the sacred writers to be mistaken. It is a common opinion, that the inspiration of the Holy Spirit regards only the matter, not the style or words; and this seems to fall in with M. Simon's doctrine of direction.

Theological writers have enumerated several kinds of inspiration. These are, an inspiration of superintendence, in which God so influences and directs the mind of any person, as to keep him more secure from error in a various and complex discourse, than he would have been merely by the use of his natural faculties; plenary superintendent inspiration, which excludes any mixture of error at all from the performance so superintended; inspiration of elevation, where the faculties act in a regular, and, as it seems, in a common manner, yet are raised to an extraordinary degree, so that the composition shall, upon the whole, have more of the true sublime or pathetic, than natural genius could have given; and inspiration of suggestion, when the use of the faculties is superseded, and God does, as it were, speak directly to the mind, making such discoveries to it as it could not otherwise have obtained, and dictating the very words in which such discoveries are to be communicated, if they are designed as a message to others. It is generally allowed that the New Testament was written by a superintendent inspiration. Without this the discourses and doctrines of Christ could not have been faithfully recorded by the evangelists and apostles; nor could they have assumed the authority of speaking the words of Christ, or evinced this authority by the actual exercise of miraculous powers. Besides, the sacred writings bear many obvious internal marks of their divine original, in the excellence of their doctrines, the spirituality and elevation of their design, the majesty and simplicity of their style, the agreement of their various parts, and their efficacy on mankind; to which may be added, that there has been in the Christian Church, from its earliest ages, a constant tradition that the sacred books were written by the extraordinary assistance of the Spirit, which must at least amount to superintendent inspiration. But it has been controverted whether this inspiration extended to every minute circumstance in their writings, so as to be in the most absolute sense plenary. Jerome, Grotius, Erasmus, Episcopius, and many others, maintain that it was not; whilst others contend, that the emphatical manner in which our Lord speaks of the agency of the Spirit upon them, and in which they themselves speak of their own writings, fully justify our believing that their inspiration was plenary, unless there be convincing evidence brought on the other side to prove that it was not. If it be said we allow that there were some errors in the New Testament, as it came from the hands of the apostles, there may be great danger of subverting the main purpose and design of that book; since there will be endless room to debate the importance both of facts and doctrines.

Inspiration, in *Physic*, is understood of that action of the breast, by which the air is admitted into the lungs; in which sense, inspiration is a branch of respiration, and stands opposed to *Exspiration*.

INSPISSATING, in *Pharmacy*, an operation by which a liquor is brought to a thicker consistence, by evaporating the thinner parts.

INSPRUCK or INSBRUCK, a city, the capital of the province of Tyrol, in the Austrian dominions. It is situated on the river Inn, where the Sill falls into that stream. Though not a strong it is a large city, containing twenty-one churches, two hospitals, an orphan house, several monasteries, and within the walls 1925 families, consisting of 10,237 individuals; the suburbs also are extensive and populous. It contains a gymnasium, with a good library, and fifteen professors in the several branches of theology, jurisprudence, medicine, and philosophy. It has manufactures of muslins and cambrics, and also of cutlery and other metallic wares. The house of the provincial government is a fine antique building, as is likewise the town-hall. It is in Lat. 47° 16′ 8″, and Long. 11° 18′ 22″ E.

INSTALLATION, the act of giving visible possession of an order, rank, or office, by placing the person collated or appointed in the proper seat.

INSTALMENT, a settling or instating any person in a dignity. The word is derived from the Latin *in* and *stallum*, a term used for a seat in church, in the choir, or a seat or bench in a court of justice, though Vossius is of opinion that the word is of German origin.

Instalment is likewise used for the ceremony by which the Knights of the Garter are placed in their rank, in the chapel of St George at Windsor.

INSTANT, a part of duration in which we perceive no succession; or it is that which takes up the time only of one idea in our minds.

INSTAURATION, the re-establishment or restoration of a religion, a church, or the like, to its former state. The word is by some derived from the old Latin *instaurum*, which signified the stock of things necessary for the tilling and managing of grounds, as cattle, tools, harness, and the like. But the word *instaurum* is only of the middle age; whilst *instauratio* is of much greater antiquity, and by some derived from *instar*, like, as importing a thing's being brought to its former likeness or appearance.

INSTERBURG, a city of the circle of the same name in the Gumbinen division of the province of East Prussia. It stands near the junction of the river Angerap with the Inster, by which the navigable river Pregel is formed. It contains two churches, 465 houses, and 5870 inhabitants. There are some manufacturers of cloth, linen, and hosiery. It is the seat of the several courts of justice for the ancient districts, which were a part of Lithuania. Lat. 54° 37′ 16″; Long. 21° 34′ 1″ E.

INSTINCT, a certain power or disposition of mind, by which, independently of all instruction or experience, without deliberation, and without having any end in view, animals are unerringly directed to do spontaneously[1] whatever is necessary for the preservation of the individual, or the continuation of the kind. Such in the human species is the instinct of sucking exerted immediately after birth; and such in the inferior creation is the instinct by which insects invariably deposit their eggs in situations most favourable for hatching and affording nourishment to their future progeny. These operations are necessary for the preservation of the individual and the continuation of the kind; but neither the infant nor the insect knows that they are necessary; they both act without having any end in view, and act uniformly without instruction and without experience.

The actions of the inferior animals are generally directed by instinct; those of man by reason. This, at least, is the case with respect to men in a state of civilization. In the savage state, they are probably little less the slaves of instinct than the brutes themselves. Concerning *human* instincts, indeed, philosophers differ widely in opinion; some maintaining that man is endowed with a greater number of instincts than any species of brutes, whilst others deny that in human nature there is any power or propensity at all which can properly be called instinctive.

This diversity of opinion may easily be traced to its source. There are not many original thinkers in the world. The greater part even of those who are called philosophers implicitly adopt the opinions of certain masters, whose authority they deem sufficient to supply the place of argument; and having chosen their respective guides, each maintains with zeal what his master taught, or is supposed to have taught. When Locke so successfully attacked the doctrine of innate ideas and innate principles of speculative truth, he was thought by many to have overturned at the same time all innate principles whatever; to have divested the human mind of every passion, affection, and instinct; and to have left in it nothing but the powers of sensation, memory, and intellect. Such, we are persuaded, was not his intention; nor is there any thing in his immortal work which, when interpreted with candour, appears to have such a tendency.

In our opinion, great part of the Essay on Human Understanding has been very generally misunderstood. Much of its merit, however, was soon discovered; and mankind, finding philosophy disencumbered of the barbarous jargon of the schools, and built upon a few self-evident principles, implicitly embraced every opinion advanced, or which they supposed to be advanced, by the illustrious author; especially if that opinion was contrary to any part of the scholastic system which had so long been employed to perplex the understanding, and to veil absurdity. Hence arose many philosophers of eminence, both at home and abroad, who maintained, as they imagined, upon the principles of Locke, that in the human mind there are no instincts, but that every thing which had been usually called by that name is resolvable into association and habit. This doctrine was attacked by Lord Shaftesbury, who introduced into the theory of mind, as faculties derived from nature, a sense of beauty, a sense of honour, and a sense of ridicule; and these he considered as the tests of speculative truth and moral rectitude. His Lordship's principles were in part adopted by Mr Hutcheson of Glasgow, who published a system of moral philosophy, founded upon a sense or instinct, to which he gave the name of the *moral sense*; and the undoubted merit of his work procured him many followers.

Men generally run from one extreme to another. It being now discovered, or at least supposed, that the human mind is endowed with instinctive principles of action, a sect of philosophers soon afterwards arose, who maintained with much vehemence that it is likewise endowed with instinctive principles of belief; and who built a system of metaphysics, if such it may be called, upon a number of innate, distinct, and independent senses. The rise of this sect is well known. Berkeley and Hume had adopted Locke's doctrine respecting the origin of our ideas; and had thence deduced consequences supposed to be dangerous in themselves, but which, it was thought, could not be denied without refusing the principles from which they were inferred. The foundation of the instinctive system being thus laid, the system itself was rapidly carried to a height far beyond what seems to have been the intention of its excellent author; and reason was well nigh banished from the regions of philosophy. For such a proceeding it is not difficult to assign the cause. The instinctive scheme requires much less labour of investigation than the systems of Locke

[1] As nothing is of greater importance in the philosophy of mind than accurate definitions, it may not be improper to observe, that throughout the whole of this article the word *spontaneous* is to be taken in the sense in which it is used in the following extracts from Hales's *Origin of Mankind*: "Many analogical motions in animals, though I cannot call them *voluntary*, yet I see them *spontaneous*. I have reason to conclude, that these are *not* simply *mechanical*." "The sagacities and instincts of brutes, the *spontaneousness* of many of their motions, are not explicable, without supposing some active determinate power connected to and inherent in their spirits, of a higher extraction than the bare natural modification of matter." If this be attended to, our definition of instinct will be found perfectly consonant to that which has been given by the author of *Ancient Metaphysics*: "Instinct," he says, "is a determination given by Almighty Wisdom to the mind of the brute, to act in such or such a way, upon such or such an occasion, without intelligence, without knowledge of good or ill, and without knowing for what end or purpose he acts."

and the ancients; for upon the principles of it, when carried to its utmost extent, every phenomenon in human nature is thought to be sufficiently accounted for, by supposing it the effect of a particular instinct implanted in the mind for that very purpose. Hence, in some popular works of philosophy, we have a detail of so many distinct internal senses, that it requires no small strength of memory to retain their very names. Besides the *moral sense*, we have the sense of *beauty*, the sense of *deformity*, the sense of *honour*, the *hoarding* sense, and a thousand others which it is needless here to mention.

This new system, which converts the philosophy of mind into mere history, or rather into a collection of facts and anecdotes, though it has made a rapid progress, is not yet universally received. It has been opposed by many speculative men, and by none with greater skill than Dr Priestley, who maintains, with the earliest admirers of Locke, that we have from nature no innate sense of truth, nor any instinctive principle of action; that even the action of sucking, in new-born infants, is to be accounted for upon principles of mechanism; and that the desire of the sexes is merely association.

Whilst men, eminent for candour as well as for science, have thus been disputing the limits between instinct and reason in the human mind, and endeavouring to ascertain the actions which result from each, two writers of name, treating of that subject, have advanced opinions, which, if admitted as just, must render the dispute henceforth ridiculous, and put an end for ever to all moral inquiries. Mr Smellie, in a work which he calls the Philosophy of Natural History, affirms that, between *instinctive* and *rational motives*, no distinction exists, but that the reasoning faculty itself is the necessary result of instinct; and Dr Reid, in his Essays on the Active Powers of Man, by attributing to instinct the action of breathing, seems to confound that principle with mere mechanism.

That reason, instinct, and mechanism, are all essentially different from one another, has hitherto been universally allowed; and it appears not to be a task of much difficulty to point out in what respect each of them differs from the other two. Actions performed with a view to accomplish a certain end are called *rational* actions, and the end in view is the *motive* to their performance. *Instinctive* actions have a *cause*, viz. the internal impulse by which they are spontaneously performed; but they cannot be said to have a *motive*, because they are not done with any view to consequences. Actions *automatic* have likewise a cause; but that cause is not internal impulse, but mere mechanism, by which they are performed without any spontaneity of the agent. Thus, a man gives charity in order to relieve a person from want; he performs a grateful action as a duty incumbent on him; and he fights for his country in order to repel its enemies. Each of these actions is performed from a motive, and therefore they are all rational actions. An infant is impelled to suck the breast, but he knows not that it is necessary for his preservation; a couple of young savages go together, for the first time, without any view to offspring, or any determinate idea of enjoyment. These actions have no motive, and therefore are not rational; but as they are performed by a spontaneous exertion of the agents, they are not to be attributed to mere mechanism; they are therefore instinctive actions. A man breathes without any motive, without any spontaneous exertion of his own, and that as well when he is asleep as when he is awake. The action of breathing, therefore, is neither rational nor instinctive, but merely automatic or mechanical. All this seems to be very plain. To talk of the motives of actions performed by instinct, in an argument intended to prove that between reason and instinct there is no difference, is either to beg the question or to pervert language. If the author of the Philosophy of Natural History chooses to call the impulse which prompts the infant to suck by the name of *motive*, he only uses an English word improperly; if it be his intention to affirm that such a motive is not totally and essentially different from that which prompts a man to give charity or to fight for his country, he affirms what all mankind know to be false.[1]

Having thus ascertained what we mean by instinct, we shall now proceed to inquire, Whether or not there be any instinctive principles in man? But in order to proceed upon sure grounds, it will be proper to consider, in the first place, such actions of the inferior animals as are generally allowed to be instinctive: for an attempt has lately been made to prove, that even these actions are the offspring of reason influenced by motives; and that instinct, as we have defined it, is a mere imaginary principle, which has no existence either in man or brute.

It has been said that caterpillars, when shaken off a tree in every direction, instantly turn round towards the trunk and climb up, though they had never formerly been on the surface of the ground. This is a striking instance of instinct. On the tree, and not upon the ground, the caterpillar finds its food. If, therefore, it did not turn and climb up the trunk it would inevitably perish; but surely the caterpillar knows not that such an exertion is necessary to its preservation; and therefore it acts not from motives, but from blind impulse. The bee and the beaver are endowed with an instinct which has the appearance of foresight. They build magazines, and fill them with provisions; but the foresight is not theirs. Neither bees nor beavers know any thing of futurity. The solitary wasp digs holes in the sand, in each of which she deposits an egg. Though she certainly knows not that an animal is to proceed from that egg, and still less, if possible, that this animal must be nourished with other animals, she collects a few small green worms, which she rolls up in a circular form, and fixes in the hole in such a manner that they cannot move. When the wasp-worm is hatched, it is amply stored with the food which Nature has destined for its support. The green worms are devoured in succession; and the number deposited is exactly proportioned to the time necessary for the growth and transformation of the wasp-worm into a fly; when it issues from the hole, and is capable of procuring its own nourishment. This instinct of the parent-wasp is the more remarkable, that she feeds not upon flesh herself. Birds of the same species, unless when restrained by peculiar circumstances, uniformly build their nests of the same materials, and in the same form and situation, though they in-

---

[1] The author of *Ancient Metaphysics*, whose learned work contains much good sense on this subject, thus distinguishes between reason and instinct: "With respect to the mere animal, it is evident, that he pursues nothing but what is conducive either to the preservation of the animal life, or to the continuation of the kind. On the other hand, the object which the intellectual mind pursues, is the *fair* and the *handsome*, and its happiness consists in the contemplation of these. And though it pursue also what is *useful* and *profitable* for the being and well-being of the animal life, yet it is for the sake, not of the animal life itself, but of the το καλον, or *beautiful*; which, therefore, is the ultimate object of its pursuit in all things.

"Another material difference in practice betwixt the animal and intellectual mind is, that every action of intellect proceeds from an opinion formed concerning what is good or ill, beautiful or the contrary, in the action. When we do so, we are said to act from *will*, which is always determined by some opinion formed of the kind I have mentioned: whereas, when we act from mere appetite or inclination, without deliberation or opinion formed, we act as the brute does always; for he has no *will*, but is prompted to action by natural impulse, or ὁρμη, as the Greeks call it.

"A third very material difference is, that intellect, in all its operations, proposes ends, and devises means to accomplish these ends; whereas the instinct of the brute proceeds without consideration either of ends or means."

habit very different climates; and the form and situation are always suited to their nature, and calculated to afford them shelter and protection. When danger, or any other circumstance peculiar to certain countries, renders a deviation from the common form and situation of nests necessary, that deviation is made in an equal degree, and in the very same manner, by all the birds of one species; and it is never found to extend beyond the limits of the country where alone it can serve any good purpose. When removed by necessity from their eggs, birds return to them with haste and anxiety, and shift them so as to heat them equally; and it is worthy of observation, that their haste to return is always in proportion to the cold of the climate. But do birds reason, and all of the same species reason equally well, upon the nature and extent of danger, and upon the means by which it can best be avoided? Have birds any notion of equality, or do they know that heat is necessary for incubation? No. In all these operations men recognise the intentions of nature; but they are hid from the animals themselves, and therefore cannot operate upon them as motives.

Of the instinct of animals we shall give one instance more in the elegant and perspicuous language of Dr Reid. "Every manufacturing art among men," says that able writer, "was invented by some man, improved by others, and brought to perfection by time and experience. Men learn to work in it by long practice, which produces a habit. The arts of men vary in every age and in every nation, and are found only in those men who have been taught them. The manufactures of animals differ from those of men in many striking particulars. No animal of the species can claim the invention; no animal ever introduced any new improvement, or any variation from the former practice; every one of the species has equal skill from the beginning, without teaching, without experience, and without habit; every one has its art by a kind of inspiration. I do not mean that it is inspired with the principles or rules of the art, but with the ability of working in it to perfection, without any knowledge of its principles, rules, or end. The work of every animal is indeed like the works of nature, perfect in its kind, and can bear the most critical examination of the mechanic or the mathematician; of which a honeycomb is a striking instance.

"Bees, it is well known, construct their combs with small cells on both sides, fit both for holding their store of honey and for rearing their young. There are only three possible figures of the cells, which can make them all equal and similar, without any useless interstices. These are the equilateral triangle, the square, and the regular hexagon. Of the three, the hexagon is the most proper, both for convenience and strength. Bees, as if they knew this, make their cells regular hexagons. As the combs have cells on both sides, the cells may either be exactly opposite, having partition against partition, or the bottom of the cell may rest upon the partitions between the cells on the other side, which will serve as a buttress to strengthen it. The last way is the best for strength; accordingly the bottom of each cell rests against the point where three partitions meet on the other side, which gives it all the strength possible. The bottom of a cell may either be one plane, perpendicular to the side partitions; or it may be composed of several planes, meeting in a solid angle in the middle point. It is only in one of these two ways that all the cells can be similar without losing room. And, for the same intention, the planes, of which the bottom is composed, if there be more than one, must be three in number, and neither more nor fewer. It has been demonstrated, that by making the bottoms of the cells to consist of three planes meeting in a point, there is a saving of material and labour no way inconsiderable. The bees, as if acquainted with these principles of solid geometry, follow them most accurately: the bottom of each cell being composed of three planes, which make obtuse angles with the side partitions, and with one another, and meet in a point in the middle of the bottom; the three angles of this bottom being supported by three partitions on the other side of the comb, and the point of it by the common intersection of these three partitions. One instance more of the mathematical skill displayed in the structure of a honeycomb deserves to be mentioned. It is a curious mathematical problem, at what precise angle the three planes which compose the bottom of a cell ought to meet, in order to make the greatest possible saving of material and labour. This is one of those problems belonging to the higher parts of mathematics, which are called problems of *maxima* and *minima*. The celebrated Maclaurin resolved it by a fluxionary calculation, which is to be found in the Transactions of the Royal Society of London, and determined precisely the angle required. Upon the most exact mensuration which the subject could admit, he afterwards found, that it is the very angle in which the three planes in the bottom of the cell of a honeycomb do actually meet.

"Shall we ask here, Who taught the bees the properties of solids, and to resolve the problems of *maxima* and *minima*? If a honeycomb were a work of art, every man of common sense would conclude, without hesitation, that he who invented the construction must have understood the principles on which it was constructed. We need not say that bees know none of these things. They work most geometrically without any knowledge of geometry; somewhat like a child, who by turning the handle of an organ makes good music without any knowledge of music. The art is not in the child, but in him who made the organ. In like manner, when a bee makes its comb so geometrically, the geometry is not in the bee, but in that great Geometrician who made the bee, and made all things in number, weight, and measure."

We have given a full detail of the structure of a honeycomb, because it is an effect of instinct which cannot be confounded with the operations of reason. The author of the Natural History of Animals, justly offended with that theory which treats of instinctive motives, which represents the human mind as a bundle of instincts, and of which the object seems to be to degrade mankind to the level of brutes, has very laudably exerted his endeavours to detect its weakness, and to expose it to contempt. But in avoiding one extreme, he seems to have run into the other; and whilst he maintains the rights of his own species, he almost raises the brutes to the rank of men. "It is better (he says) to share our rights with others than to be entirely deprived of them." This is certainly true; and no good man will hesitate to prefer his theory to that of his antagonist; but we see no necessity for adopting either; the phenomena may be accounted for without degrading reason to the level of instinct, or elevating instinct to the dignity of reason.

We shall readily allow to Locke,[1] that some of the inferior animals seem to have perceptions of particular truths,

[1] "For if they have any ideas at all, and are not mere machines, as some would have them, we cannot deny them to have some reason. It seems as evident to me, that some of them do, in certain instances, reason, as that they have sense; but it is only in particular ideas, just as they received them from the senses. They are the best of them tied up within those narrow bounds, and have not, as I think, the faculty to enlarge them by any kind of abstraction." (*Essay on Human Understanding*, book ii. chap. xi.)

This is in part a just observation, and serves to account for many phenomena which later writers have derived from instinct. The author of *The Philosophy of Natural History* had "a cat that frequented a closet, the door of which was fastened by a common iron latch. A window was situated near the door. When the door was shut, the cat gave herself no uneasiness. As soon as she tired of and within very narrow limits the faculty of reason; but we see no ground to suppose that their natural operations are performed with a view to consequences; and therefore cannot persuade ourselves with this historian of theirs, that these operations are the result of a train of reasoning in the mind of the animal.

He acknowledges, indeed, that their reasoning and thinking powers are remarkably deficient when compared with those of men; that they cannot take so full a review of the past, nor look forward with so penetrating an eye to the future; that they do not accumulate observation upon observation, nor add the experience of one generation to that of another; that their manners do not vary, nor their customs fluctuate like ours; and that their arts always remain the same, without degeneracy and without improvement. "The crow," he observes, "always builds its nest in the same way; every hen treats her young with the same measure of affection; even the dog, the horse, and the sagacious elephant, seem to act rather mechanically than with design. From such hasty observations as these, it has been inferred," he says, "that the brutes are directed in their actions by some mysterious influence, which impels them to employ their powers unintentionally in performing actions beneficial to themselves, and suitable to their nature and circumstances."

And are these observations indeed hasty? and is this inference ill founded? To us the matter appears quite otherwise. If the arts of brutes and other animals have always remained the same without degeneracy, and without improvement; and if they be at the same time the result of reasoning, they must either be so perfect that they cannot be improved, or so imperfect that they cannot degenerate. That the structure of a honeycomb is imperfect no man has ever imagined. We have seen, that as far as we are capable of discerning the end which it is intended to serve, it is the most perfect structure possible; and, therefore, if it be the result of the reasoning of the bee, the author must retract his assertion respecting the extent of the reasoning and thinking powers of inferior animals; and instead of saying that they are remarkably deficient when compared with those of men, affirm that they are infinitely more perfect. No human art has yet arrived at such perfection as that it might not be improved; no architect has ever built a town, or constructed a magazine, which he could mathematically demonstrate to be of the very best possible form for the end intended, and so absolutely perfect as to be incapable of improvement.

But the same author proceeds to affirm, that "the laws of analogical reasoning do not justify the idea that the brutes act, on any occasion, absolutely without design." Nay, he says, it seems more probable "that the inferior animals, even in those instances in which we cannot distinguish the motives which actuate them, or the views with which they proceed, yet act with design, and extend their views, if not a great way, yet at least a certain length forward; than that they can be upon any occasion, such as in rearing of their young, building nests, &c., actuated merely by feeling, or overruled by some mysterious influence, under which they are nothing but insensible instruments." This last phrase is ambiguous. If by insensible instruments it be meant that the brutes are considered by the advocates for instinct as mere machines without the faculties of sensation and spontaneity, the author is combating a phantom of his own creation; for we believe an opinion so absurd is not now maintained by any man (see Brute). But if by insensible instruments be meant such instruments as act spontaneously without being conscious of the end to which their actions lead, he appears not only to be egregiously mistaken in his conjecture respecting the design of brutes, but also to have advanced an hypothesis contradictory and inconsistent.

If it be true that the inferior animals act with design, even in those instances in which we cannot distinguish their motives, their views may indeed extend but a little way when compared with infinity: but certainly they extend farther than ours; for there is no useful work of man constructed with such skill, but that, after it is finished, another man of equal education will be able to distinguish the general design of the artist. But if the inferior animals, on all occasions, act with design, we should be glad to know the design of the bees in forming the cells of their combs in the manner which we have so largely described. Do these little animals indeed know that a comb, consisting on both sides of hexagonal cells, with the bottom of each composed of several planes meeting in a certain solid angle, and so formed as that the bottom of a cell on the one side shall rest upon the partitions between the cells on the other side, is in all respects the most proper both for holding their stores of honey and for rearing their young? And do they likewise know, that its excellence arises from the precise figure and position of the cells, by which there is a very considerable saving of labour and materials, whilst the comb at the same time has the greatest possible strength, and the greatest possible capaciousness? If they know all this, and act with a view to these ends, it must indeed be confessed that bees are rational creatures, and that their thinking and reasoning powers far surpass those of men; for they have from the earliest ages made discoveries in the higher mathematics, which there is reason to believe were altogether unknown to the human race till the begin-

---

her confinement, she mounted on the sole of the window, and with her paw dexterously lifted the latch and came out." This practice, which we are told continued for years, must have been the consequence of what Locke calls reasoning in particular ideas. It could not be the effect of instinct; for instinct is adapted only to a state of nature, in which cats have neither latches to lift nor doors to open; and as it is not said that the animal attempted to lift the latches of other doors, we are not authorized to infer that this particular action was the consequence of reasoning in ideas enlarged by abstraction: the cat had repeatedly seen one door opened by an exertion which she was capable of imitating. Yet that animals have no power of enlarging their ideas, is a position, of the truth of which, though it is advanced by Locke, we are by no means confident. It is well known that crows feed upon several kinds of shell-fish when within their reach; and that they contrive to break the shell by raising the fish to a great height, and letting it drop upon a stone or a rock. This may perhaps be considered as pure instinct directing the animal to the proper means of acquiring its food. But what is to be thought of the following fact, which was communicated to us by a gentleman whose veracity is unquestioned, and who, being totally unacquainted with the theories of philosophers, has of course no favourite hypothesis to support? In the spring of the year 1791, a pair of crows made their nest in a tree, of which there were several planted round his garden; and in his morning walks he had often been amused by witnessing furious combats between them and a cat. One morning the battle raged more fiercely than usual, till at last the cat gave way, and took shelter under a hedge, as if to wait a more favourable opportunity of retreating to the house. The crows continued for a short time to make a threatening noise; but perceiving that on the ground they could do nothing more than threaten, one of them lifted a stone from the middle of the garden, and perched with it on a tree planted in the hedge, where she sat watching the motions of the enemy of her young. As the cat crept along under the hedge, the crow accompanied her by flying from branch to branch and from tree to tree; and when at last puss ventured to quit her hiding-place, the crow, leaving the tree, and hovering over her in the air, let the stone drop from on high on her back. That the crow on this occasion reasoned, is self-evident; and it seems to be little less evident, that the ideas employed in her reasoning were enlarged beyond those which she had received from her senses. By her se ses, she may have perceived, that the shell of a fish is broken by a fall; but could her senses inform her, that a cat would be wounded or driven off the field by the fall of a stone? No. From the effect of the one fall preserved in her memory, she must have inferred the other by her power of reasoning.

Instinct.

ning of the present century, and which at this moment are beyond the comprehension of nine-tenths of mankind in the most enlightened nation on earth. If this be a conclusion too absurd to be admitted, there is no other alternative but either to suppose that by this artificial structure of their cells the bees have some other end in view, which we cannot distinguish; or to acknowledge that they are overruled by some mysterious influence, under which they are nothing but spontaneous agents, unconscious of the end to which their operations tend. Which of these conclusions is the most rational, we will not offer such an insult to the understanding of our readers, as to suppose the meanest of them capable of entertaining a doubt. That a honeycomb is constructed with design, we must readily admit; but the design is not in the bees, but in the Creator of the bees, who directs their operations to their own good, by what the author with great propriety terms a mysterious influence.[1]

But he thinks it an unanswerable argument in support of his theory, that in the performance of those actions, in which animals are said to be guided by unerring instinct, different individuals display different modes of conduct; and in his opinion, to talk of instinctive principles which admit of improvement, and accommodate themselves to circumstances, is merely to introduce new terms into the language of philosophy; for he affirms, that no such improvement or accommodation to circumstances can ever take place without a comparison of ideas and a deduction of inferences. It is probable that the author here alludes to those animals which, in their most important operations, are known to act differently in different countries. Thus the ostrich in Senegal, where the heat is excessive, neglects her eggs during the day, but sits upon them in the night. At the Cape of Good Hope, however, where the degree of heat is less, the ostrich, like other birds, sits upon her eggs both day and night. In countries infested with monkeys, many birds, which in other climates build in bushes and clefts of trees, suspend their nests upon slender twigs, and thus elude the rapacity of their enemies.

It may be thought, that a determination of the mind of the brute to act so variously upon different occasions, can hardly be conceived without judgment or intelligence. But before our author had so confidently affirmed that such accommodation to circumstances can never take place without a comparison of ideas and a deduction of inferences, he would have done well to consider how nature acts in other organized bodies, such as the vegetable. We see that a vegetable, reared in the corner of a dark cellar, will bend itself towards the light which comes in at the window; and if it be made to grow in a flower-pot, with its head downwards, it will turn itself into the natural position of a plant. Can it be supposed, that the plant, in either case, does what it does from any judgment or opinion that it is best, and not from a necessary determination of its nature? But, further, to take the case of bodies unorganized, how shall we account for the phenomena which chemistry exhibits to us? When one body unites with another, and then, upon a third being presented to it, quits the first, and unites itself with it, shall we suppose that this preference proceeds from any predilection or opinion that it is better to cleave to the one than to the other, from any comparison of ideas or deduction of inferences? Or shall we not rather say, that it proceeds from an original law of nature impressed upon it by that Being who mediately or immediately directs every motion of every the minutest atom in the universe? And if so, why may not instinct be an original determination of the mind of the animal, of which it is part of the nature or essence to accommodate itself to certain circumstance, on which depends the preservation of the individual, or the continuation of the kind? Indeed it cannot be otherwise, if we have defined instinct properly; for no man ever supposed, that when animals work instinctively, they act for no purpose. It is only affirmed that the purpose is not known to them. It is known, however, to the Author of instinct; who knows likewise that the same purpose must in different climates be promoted by different means, and who accordingly determines the operations of animals of the same species to be different under different circumstances.

But though we cannot agree with this author when he affirms that no accommodation to circumstances can ever take place without a comparison of ideas, we readily admit that no faculty which is capable of improvement by observation and experience can in propriety of speech be termed instinct. Instinct being a positive determination given to the minds of animals by the Author of nature for certain purposes, must necessarily be perfect when viewed in connection with those purposes; and therefore to talk, as Mr Smellie does, of the *improvement* of instinct, is to perplex the understanding by a perversion of language. There is not, however, a doubt, but that reason may copy the works of instinct, and so far alter or improve them as to render them subservient to other purposes than those for which they were originally and instinctively performed. It was thus in all probability that man at first learned many of the most useful arts of life.

> Thy arts of building from the bee receive;
> Learn of the mole to plough, the worm to weave;
> Learn of the little nautilus to sail,
> Spread the thin oar, and catch the driving gale.

But the arts thus adopted by men are no longer the works of instinct, but the operations of reason influenced by motives. This is so obviously and undeniably true, that it has compelled the author last mentioned to confess, in that very section which treats of instincts improvable by experience, that "what men or brutes learn by experience, though this experience be founded on instinct, cannot with propriety be called instinctive knowledge, but knowledge derived from experience and observation. Instinct (he says) should be limited to such actions as every individual of a species exerts without the aid either of experience or imitation." This is a very just distinction between instinct and experience; but how to reconcile it with the fundamental principle of the author's theory we know not. It would certainly be a very arduous task; but it is a task from which we are happily relieved, as his theory and our's have little resemblance.

Having thus proved, we hope to the satisfaction of our readers, that there is such a principle as instinct in the inferior animals, and that it is essentially different from human reason, let us return to our own species, and inquire whether there be any occasions upon which man acts instinctively, and what these occasions are. This is a question of some difficulty, to which a complete and satisfactory answer will perhaps never be given, and to which we have not the vanity to think that such an answer will be given by us. The principle of association operates so powerfully in man, and at so early a period of life, that in many cases it seems to be impossible to distinguish the effects of habit from the operations of nature. Yet there are a few cases, immediately connected with the preservation of the individual and the propagation of the kind, in which by a little attention these things may be distinguished. We

[1] Though this way of acting is undoubtedly mysterious, "yet it should not appear extraordinary even to a man who is not a philosopher. as we see examples of it daily in our own species; for a man under the direction of another of superior understanding, will use means to accomplish an end, without having an idea of either; and indeed, in my opinion, by far the greater part of mankind are destined by God and nature to be governed in that way." (*Ancient Metaphysics*, vol. iii. p. 352.)

have already given an instance in the sucking of a child, which we believe to be an operation performed by instinct. Dr Priestley, however, thinks differently. "The action of sucking," says he, "I am confident, from my own observation, is not natural, but acquired." What observations they were which led him to this conclusion he has not told us, and we cannot imagine; but every observation which we ourselves have made, compels us to believe that an attempt to suck is natural to children. It has been observed by the author of the Philosophy of Natural History, that the instinct of sucking is not excited by any smell peculiar to the mother, to milk, or to any other substance; for that infants suck indiscriminately every thing brought into contact with their mouths. He therefore infers, that the *desire* of sucking is innate, and coeval with the appetite for air. The observation is certainly just; but a disciple of Dr Priestley's may object to the inference; for "in sucking and swallowing our food, and in many such instances, it is exceedingly probable," says the doctor, "that the actions of the muscles are originally automatic, having been so placed by our Maker, that at first they are stimulated and contract mechanically whenever their action is requisite." This is certainly the case with respect to the motion of the muscles in the action of breathing; and if that action be of the same kind and proceed from the very same cause with the action of sucking, and if a child never shew a desire to suck but when something is brought into contact with its mouth, Dr Priestley's account of this operation appears to us much more satisfactory than that of the authors who attribute it to instinct.

But the actions of breathing and sucking seem to differ essentially in several particulars. They are indeed both performed by means of air; but in the former, a child for many months exerts no spontaneous effort, whilst a spontaneous effort seems to be absolutely necessary for the performance of the latter. Of this indeed we could not be certain, were it true that infants never exhibit symptoms of a wish to suck but when something is exactly in contact with their mouths; for the mere act of sucking then might well be supposed to be automatic and the effect of irritation. But this is not the case. A healthy and vigorous infant, within ten minutes of its birth, gives the plainest and most unequivocal evidence of a desire to suck, before any thing be brought into actual contact with its mouth. It stretches out its neck, and turns its head from side to side apparently in quest of something: and that the object of its pursuit is something which it may suck, every man may satisfy himself by a very convincing experiment. When an infant is thus stretching out its neck and moving its head, if any thing be made to touch any part of its face, the little creature will instantly turn to the object, and endeavour by quick alternate motions from side to side to seize it with its mouth, in the very same manner in which it always seizes the breast of its nurse, till taught by experience to distinguish objects by the sense of sight, when these alternate motions, being no longer useful, are no longer employed. If this be not an instance of pure instinct, we know not what it is. It cannot be the result of association or mechanism; for when the stretching of the neck takes place, nothing is in contact with the child's mouth, and no association which includes the act of sucking can have been formed. Associations of ideas are the consequences of simultaneous impressions frequently repeated; but when the child first declares, as plainly as it could do were it possessed of language, its wish to suck, it has not received a single impression with which that wish can possibly be associated.

Were Dr Priestley to weigh these facts, of the truth of which we are certain, we doubt not that his well-known candour would make him retract the assertion, that all the actions which Dr Reid and others refer to instinct, are either automatic or acquired. The greater part of those actions, as well as of the apparently instinctive principles of belief, we have no doubt are acquired; but we are persuaded that a child sucks its nurse as a bee builds its cell, by instinct; for upon no other hypothesis can we account for the spontaneous efforts exerted in both these operations; and we think it no disgrace to our species, that in some few cases we should act from the same principle with the inferior creation, as nothing seems more true than that,

—— Reason raise o'er instinct as we can;
In this 'tis God that works, in that 'tis man.

We have said that, in the savage state, the sexes go together for the first time by instinct, without any view to offspring, and perhaps with no determinate idea of enjoyment. This opinion, we believe, has been generally maintained; but it is controverted by Dr Hartley. "Here," says he, "we are to observe, first, that when a general pleasurable state is introduced, either by direct impressions or by associated influences, the organs of generation must sympathize with this general state, for the same reasons as the other parts do. They must therefore be affected with vibrations in their nerves, which rise above indifference, into the limits of pleasure, from youth, health, grateful aliment, the pleasures of imagination, ambition, and sympathy, or any other cause which diffuses grateful vibrations over the whole system. Secondly, as these organs are endued with a greater degree of sensibility than the other parts, from their make, and the peculiar structure and disposition of the nerves, whatever these be, we may expect that they should be more affected by those general pleasurable states of the nervous system than the other parts. Thirdly, the distension of the cells of the *vesiculæ seminales* and of the sinuses of the *uterus*, which take place about the time of puberty, must make these organs more particularly irritable then." His fourth observation respects a state widely different from that of nature, and therefore is nothing to the purpose: but his fifth is, that "the particular shame which regards the organs of generation, may, when considered as an associated circumstance, like other pains, be so far diminished as to fall within the limits of pleasure, and add considerably to the sum-total."

To this excellent and able writer we may allow the truth of these observations, though some of them might certainly be controverted; and yet deny his conclusion, that "they are sufficient to account for the general desires which are observable in young persons, and that those desires are of a factitious nature." For supposing every thing which he mentions to take place by mere mechanism and association; that the organs of generation are irritated, and certain cells and sinuses distended; the only inference which can be fairly drawn from such premises is, that at the age of puberty young men and women must, from these causes, experience certain feelings and wants which they knew not before; but surely mechanism and association cannot teach them the use of the organs of generation, or point out the only means by which their new feelings can be gratified; and therefore, as we see these means invariably pursued by all animals, rational and irrational, without experience and without instruction, we must refer the mutual desire of the sexes to a higher principle than mere mechanism and association; and that principle can be nothing but instinct.

Besides these, we think the action of eating may be attributed to instinct. It is certainly performed by a spontaneous exertion of the proper organs; and that exertion is first made at a time of life when we have no conception of the end which it serves to accomplish, and therefore cannot be influenced by motives. It must, indeed, be confessed, that the first act of chewing is performed by a child, not for the purpose of masticating food, but to quicken the operation of nature in the cutting of teeth; and perhaps it may be said, that the pleasing sensation of taste, which is then first experienced, and afterwards remembered, prompts the child to continue at intervals the exertion of chewing after all his teeth are cut; so that though the act of eating is not performed with a view to the mastication of food or the nourishment of the body, it may yet be performed, not from any instinctive impulse, but merely from an early and decp-rooted association. But in answer to this it is sufficient to ask, Who taught the infant that the act of chewing will quicken the operation of nature in the cutting of teeth? Not reason, surely, nor experience; for an infant knows nothing of teeth, or the manner in which they grow; and if it be granted, that for this purpose it was originally impelled by some internal and mysterious influence to perform the action of chewing, we are not inclined to deny that the operation may be continued for other purposes, by means of association.

> In human works, though laboured on with pain,
> A thousand movements scarce one purpose gain;
> In God's, one single can its end produce,
> Yet serves to second too some other use.

This is sound philosophy, confirmed by observation and daily experience; but though in the works of God one principle produces many consequences, and though perhaps there is not a principle which falls under our cognizance more fruitful than that of association, yet if it be not sufficient to account for the first act of chewing, we cannot refer to it alone as to the source of that operation. Should it be said, that the gums of an infant are at the period of cutting teeth so irritable, that the moment any thing is applied to them the jaws perform a motion merely automatic, which we mistake for the spontaneous effect of instinct, still we would ask, What prompts the child to apply every thing to its mouth? Does the irritation of the gums contract the muscles of the arm? By a bigot for mechanism this might be said, were it true that the arm of an infant, like a piece of clock-work, is always so regularly moved as to bring its hand directly into contact with its gums: but this is far from being the case; an infant makes many unsuccessful efforts to reach its mouth, and does not accomplish its purpose till after repeated trials. Perhaps it may be alleged (for when men adopt a favourite hypothesis, they will allege any thing in its support), that infants are taught to carry things to their mouths by the pleasing sensation received from the application of their nurses' breasts, and continue the practice from habit and association. But it is certain that they do not begin this practice till teeth are forming in their gums; and then they use such things as they themselves carry to their mouths very differently from the breasts of their nurse: they constantly chew and bite their rattles, though they very seldom bite their nurses. As this practice cannot be begun from a principle of association, so it appears to us that it cannot be continued upon such a principle. Were the sensation experienced by an infant when chewing a hard substance a pleasing sensation, the remembrance of the pleasure might as a motive prompt it to repeat the operation; but it is obvious, that by pressing a gum, through which a tooth is making its way, against any thing hard, the infant must experience a painful sensation; and therefore the influence which impels it to continue this operation, must be something more powerful than pleasure or pain.

These three actions, then, by which infants suck, by which they chew their food, and by which mankind are propagated, have undeniably their origin in instinct. There may be many other human actions which derive their origin from the same source; but in a state of civil society it is very difficult, if not impossible, to distinguish them from the effects of early habit.

Such, however, is the present impatience of that labour, without which effects cannot be traced to their causes, that every phenomenon in human nature, which to former philosophers would have occasioned difficulty, is now thought to be sufficiently accounted for by referring it to some instinct as its particular cause; and he who can provide himself with a sufficient number of these instincts, for the reality of which he offers no proof, seats himself in the philosopher's chair, and dreams that he is dictating a system of science, whilst he is only retailing a collection of anecdotes. A philosopher of this school has lately carried the doctrine of instinctive principles so far, as to attribute the superiority of man over the other animals chiefly to the great number of instincts with which his mind is endowed; and amongst these he reckons not, we believe, as characteristic of our species in contradistinction to other animals, but as part of the instinctive bundle in the largeness of which our superiority consists, "the voiding of urine and excrement, sneezing, retraction of the muscles upon the application of any painful stimulus, the moving of the eyelids and other parts of the body." These, he says, are effects of original instincts, and essential to the existence of young animals. With this writer instinct is sometimes represented as looking into futurity, and acting upon motives which have hitherto been considered as the province of reason and the characteristic of man: here the same instinct is confounded with irritation and mechanism; and if this mode of philosophising continue in fashion, we shall not be surprised to find men, beasts, birds, and vegetables, considered by some other writer as nothing more than different species of the same genus of beings, that are all actuated by the great and universal principle of instinct. If sneezing and the retraction of the muscles upon the application of any painful stimulus be actions of instinct, there cannot be a doubt, upon the received principles of philosophy, but that the contraction of the leaves of the sensitive plant upon the application of any stimulus proceeds likewise from instinct. Nay, a pieoe of leather must be endowed with instinct; for it too retracts upon the application of the painful stimulus of fire. All these are evidently similar effects produced by the same or similar causes; for in the operations of sneezing and retracting the muscles upon any painful application, there is not the least spontaneous exertion on our part, no co-operation of mind more than in the contraction of the leather and the plant. With respect to the voiding of urine and excrement, it is obvious that, at first, these operations are performed without any effort of spontaneity; and that a voluntary power over the muscles which are subservient to them is very gradually acquired. Urine and excrement irritate the bladder and guts, which are supplied with branches of the same nerves that supply the abdominal muscles. But it is well known that the irritation of one branch of a nerve brings on a contraction of thc muscles which are supplied by the other branches. Urine and excrement therefore are evidently expelled by the mechanical contractions of the organs of excretion; and to attribute these evacuations to instinct, is equally absurd as to say, that water or any other soft substance pent up in a vessel, and pressed equally on all sides, makes its escape by instinct through the easiest passage. It is difficult to guess what the author means by the instinctive motion of the eyelids and other parts of the body. There is a motion of the eyelids which is voluntary, and another which is involuntary. The former proceeds from some motive, to exclude too great a glare of light, or to guard the eye against a foreseen mischief, and is therefore the result of reason as distinguished from instinct: the latter is obviously the effect of association, which took place in early infancy, and produced a habit. Infants for several days after birth do not wink with their eyes upon the approach of one's hand or any other substance; but after having experienced pain from too much light, or any other thing which hurts the eye, and that pain having at first produced an automatic motion of the eyelids, the motion comes in time to be so closely associated with its cause, that the very appearance of the latter produces the former. In all this there is no instinct, nor any thing which resembles instinct: in the one case, the motion of the eyelids is in the strictest sense voluntary and rational; and in the other, it is either automatic or the effect of habit.

"The love of light," says the same writer, "is exhibited by infants at a very early period. I have remarked evident symptoms of this attachment on the third day after birth. When children are farther advanced, marks of the various passions generally appear. The passion of fear is discoverable at the age of two months. It is called forth by approaching the hand to the child's eye, and by any sudden motion or unusual noise." It has likewise been said, that "an infant may be put into a fright by an angry countenance, and soothed again by smiles and blandishments;" and "that all these are cases of pure instinct." In reply to which, we scruple not to assert with Dr Priestley, that an infant (unless by an infant be meant a child who has a good deal of experience, and of course has made many observations on the connections of things) "is absolutely incapable of terror. I am positive (says he), that no child ever shewed the least symptom of fear or apprehension till he had actually received hurts and had felt pain; and that children have no fear of any particular person or thing, but in consequence of some connection between that person or thing and the pain they have felt. If any instinct of this kind were more necessary than another, it would be the dread of fire. But every body must have observed, that infants shew no sign of any such thing; for they will as readily put their finger to the flame of a candle as to any thing else, till they have been burned. But after some painful experience of this kind, their dread of fire, though undeniably the effect of association, becomes as quick and as effectual in its operations as if it were an original instinctive principle." We moreover do not hesitate to say, with the same great philosopher, that if it were possible always to beat and terrify a child with a placid countenance, so as never to assume that appearance but in those circumstances, and always to soothe him with what we call an angry countenance, this connection of ideas would be reversed, and we should see the child frightened with a smile, and delighted with a frown. In fact, there is no more reason to believe that a child is naturally afraid of a frown, than that he is afraid of being in the dark; and of this children certainly discover no sign, till they have either found something disagreeable to them in the dark, or have been told there is something dreadful in it.

The truth of these observations is so obvious, that we doubt not but they will carry conviction to the mind of every reader. For though it should be granted, that so early as on the third day after birth children exhibit symptoms of uneasiness upon the sudden exclusion of light, it would by no means follow that the love of light is in them instinctive. Light operates upon the eye by contact, and communicates to the infant a sensation of touch. If that sensation be pleasant, the child must necessarily feel some degree of uneasiness upon its removal, just as a full-grown man must feel uneasy upon being deprived of any positive pleasure. But is sensation, or pleasure, or the removal of pleasure, pure instinct? No, surely.

Thus difficult is it to say, in many cases, what actions have their origin in instinct, and what are merely the effects of early association. But we think it may be safely affirmed, that no action, whether of man or brute, which is deliberately performed with a view to consequences, can with any propriety be said to proceed from instinct; for such actions are the effect of reason influenced by motives. Deliberation and instinct are obviously incompatible. To say with the author of the Philosophy of Natural History, "that, when we are stimulated by a particular instinct, instead of instantly obeying the impulse, another instinct arises in opposition, creates hesitation, and often totally extinguishes the original motive to action," is either to affirm what is apparently not true, or it is a gross perversion of language. Motives opposed to each other may create hesitation, and a powerful motive may counterbalance a feeble instinct; but of two or more instincts operating at the same time, and opposing each other, we have no conception. Instinct, if we choose to speak a language that is intelligible, means a certain impulse under the direction of Supreme Wisdom; and it is very little probable that such wisdom should give opposite impulses at the same instant. In the natural works of animals, which are confessedly under the influence of instinct, we perceive no symptoms of deliberation; but every one, when not interrupted by external violence, proceeds without hesitation in the direct road, to an end of which the animal itself knows nothing. The same would be the case with man were he under the guidance of instinct; and it is vain to say that the instinct of fear is daily counteracted by ambition and resentment, till it be proved that fear, ambition, and resentment, are really instincts. Of this, however, the author seems to have no doubt. Indeed, his work is so liberally stored with those principles, so useful to every man who wishes to acquire the name of a philosopher without the labour of investigation, that not only fear, ambition, and resentment, but even superstition, devotion, respect for eminent characters, avarice, hope, envy, benevolence, and sympathy, are all, in his opinion, instincts simple or modified. The origin of fear we have already seen when examining the instincts said to exhibit themselves in early infancy: let us try if we cannot trace some other individuals of this numerous family to the same source of early associations.

The case then seems to be as follows. We first perceive or suppose some real good, that is, some fitness to promote our happiness, in those things which we love or desire. Hence we annex to those things the idea of pleasure; with which they come, in time, to be so closely associated in our minds, that they cannot ever after present themselves without bringing that idea along with them. This association likewise often remains even after that which first gave rise to it is quite forgotton, or perhaps does not exist. An instance or two will make this very clear. No man can be born a lover of money; for in a state of nature money exists not: no man, therefore, can be born with our author's instinct of avarice, directed in the manner which the most common acceptation of that word denotes. Yet how many men are there in the world, who have as strong a desire for money as if that desire were innate and instinctive; who account so much money so much happiness; and who make the mere possession of gold and silver, without any thought or design of using them, the ultimate end of all their actions? This is not because the love of money is born with them, for that is impossible; but because they first perceive a great many advantages from the possession of money, whence they conceive a pleasure in having it. Hence they desire it, endeavour to obtain it, and feel an actual pleasure in obtaining and possessing it. Then, by dropping the intermediate steps between money and happiness, they join money and happiness immediately together, and content themselves with the fantastic pleasure of having it; making that which was at first pursued only as a means, be to them an ultimate end, in which consists their happiness or misery. The same might be observed concerning the thirst after knowledge, fame, ambition, and most of the various pursuits of life. These are at first entered upon with a view to some further end, but at length become habitual exercises; with which the idea of pleasure is so closely associated, that we continue the pursuit after the reason from which it was at first begun, has entirely vanished from our minds. Hence also we may account for another of our author's modified instincts, the almost diabolical feeling of envy. Mr Locke observes, that there are some men entirely unacquainted with this passion. His observations we believe to be a just one; for most men that are used to reflection, remember the time when they were first under its influence; and though they did not, it is a thing very little likely that the beneficent Author of nature should have implanted in the human mind even the seeds of an instinct, which, in the emphatic language of The Rambler, "is mere unmixed and genuine evil." Envy is that pain which arises in the mind upon observing the success or prosperity of others; not however of all others indefinitely, but only of those with whom, upon some account or other, the envious person has once had a rivalship. But of such a feeling the origin is obvious; for when two or more persons are competitors for the same thing, the success of the one necessarily tends to the detriment of the other: hence the success of the one rival is in the mind of the other closely associated with pain or misery; and this association remaining after the rivalship which occasioned it has ceased, the person in whose mind envy is thus generated, always feels pain at the success of his rival even in affairs which have no relation to the original competition. Thus it is, that we are apt to envy those persons who refuse to be guided by our judgments, or persuaded by our arguments: for this is nothing else than a rivalship about the superiority of judgment; and we take a secret pride, both to let the world see, and in imagining ourselves, that in perspicuity and strength of judgment we have no superior.

Though the principle of association will be more fully explained in another place, there is one observation which must not be omitted here; it is, that we do not always, nor perhaps for the most part, make these associations ourselves, but learn them from others in very early life. We annex happiness or misery to certain things or actions, because we see it done by our parents or companions; and acquire principles of action by imitating those whom we esteem, or by being told, by those in whom we have been taught to place confidence, that such conduct will promote our happiness, and that the reverse will involve us in misery. Hence the son too often inherits both the vices and the virtues of his father as well as his estate; hence national virtues and vices, dispositions and opinions; and hence too it is, that habits formed before the period of distinct remembrance are so generally mistaken for natural instincts.

From the whole, then, of this investigation, we think ourselves warranted to conclude, that there is an essential difference between mechanism and instinct, and between both and reason; that mankind perform actions by each of these principles, and that those actions ought to be carefully distinguished, and though the human mind is unquestionably endowed with a few instincts necessary to the preservation of the individual and the propagation of the race, that by far the greater part of those actions which are commonly said to proceed from instinct are merely the effects of early habits. We are likewise of opinion, that the present fashionable mode of referring almost every phenomenon in human nature to a particular instinct as its ultimate cause, is hurtful to science, as tending to check all further inquiry; and dangerous in morals, as making people implicitly follow, as the dictates of nature and nature's God, the absurd superstitious or impious customs of their respective countries.

Having reprinted the foregoing article, written for a former edition, as containing a pretty full view of opinions (which is one of the most useful purposes of a work of this kind) on a subject of great curiosity and interest in philosophical speculation; we cannot do better than enlarge that view, by subjoining the following admirable observations, conceived in the spirit of genuine philosophy, from Mr Stewart's comparison between the faculties of man and those of the lower animals, in the third volume of his Philosophy of the Mind.

"That the brutes are under the more immediate guidance of Nature, while man is left, in a great degree, to regulate his own destiny by the exercise of his reason, is a fact too obvious to stand in need of illustration. In what manner, indeed, Nature operates in this instance, we are wholly ignorant; but nothing can be more certain than this, that it is not by a deliberate choice, analogous to what we experience in ourselves, that the lower animals are determined to the pursuit of particular ends; nor by any process analogous to our reason that they combine means in order to attain them.

"To that unknown, but obviously intelligent, cause which guides the operations of the brutes, we give the name of Instinct, without presuming to decide the question *where* this intelligence resides;—much in the same manner in which we give the name of the letters x and y to the unknown quantities in an algebraical problem. The circumstances by which it is distinguished from reason are so remarkable, and so manifest to the most careless observer, as to preclude, among candid inquirers, the possibility of dispute. Of these circumstances, the two following seem to be the most important: 1. The uniformity with which it proceeds in all individuals of the same species; and, 2. The unerring certainty with which it performs its office prior to all experience. In both these respects the operations of *reason* or *art*, properly so called, seem to be essentially different from any thing else that is known among animated natures; inasmuch as no two individuals of our species were ever observed to employ exactly the same combinations of means (at least where the means were at all complicated) for the attainment of the same ends; and as the capacity of reason, destitute of the aid of experience, is altogether a barren and unavailing principle.

"The disposition which some late authors have shewn to explain away the operations of instinct in man, can be accounted for only by their wish to weaken the foundations of natural religion. To speak of instincts and of original propensities, we have been told, is the language of mysticism. It is, in truth, the language of genuine science, which contents itself with a statement and generalization of facts, and stops short as soon as it arrived at the limits prescribed to human curiosity. The charge of Mysticism properly falls on those who, in attempting to conceal their ignorance from themselves or from others by means of theoretical expressions, darken the study of nature by words without knowledge.[1]

"In offering these remarks, I would not be understood to disapprove of the attempts of some late authors to analyse the various operations which are commonly referred to the general principle of instinct. But I must beg leave to remind them, that how far soever we may push the analysis, we must at last arrive at some *fact*, no less wonderful than those we mean to explain. Thus, although it should be made to appear, that the actions which a child performs at birth are learned by the *fœtus in utero*, we must still ad-

[1] "What Sir Isaac Newton has said in justification of the word *gravity*, as employed in his philosophy, against the objections of those who accused him of reviving the *occult qualities* of the Aristotelians, may be applied equally to the word *instinct*, as it is used in our present argument. 'These are manifest qualities, and their causes only are *occult*. And the Aristotelians give the name of occult qualities not to manifest qualities, but to such qualities only as they *supposed* to lie hid in bodies, and to be the unknown causes of manifest effects.' (Newton's *Optics*.)

mit, as an ultimate fact, the existence of an original determination to a particular mode of action salutary or necessary to the animal; and all that we have accomplished is to refer the origin of this instinct to an earlier period in the history of the human mind.

"In a very curious and original work, published about thirty years ago, under the title of *Zoonomia*, much ingenuity has been employed, and in several instances with great success, in analyzing those phenomena which are commonly referred to instinct; more particularly in attempting to account for the wonderful efforts which the human infant is enabled to make for its own preservation the moment after its introduction to the light.[1] Thus, it is observed, that the *fœtus*, while still in the *uterus*, learns to perform the operation of swallowing, and to relieve itself, by change of posture, from the irksomeness of continued rest; and, therefore (if we admit these propositions), we must conclude, that some of the actions which infants are vulgarly supposed to perform in consequence of instincts coeval with birth, are only a continuation of actions to which they are determined at an earlier period of their being. The remark is ingenious, and probably just, but it does not prove that *instinct* is an unphilosophical term; nor does it render the operations of the infant less mysterious than they seem to be on the common supposition. It only places these operations in a new light, and, I might perhaps venture to add, in a light more striking than they were viewed in before.

"The same author has attempted to account, in a manner somewhat similar, for the different degrees in which the young of the different animals are able, at the moment of birth, to exert their bodily powers. Thus calves and chickens are able to walk almost immediately, while the human infant, even in the most favourable situations, is six or even twelve months old before he can stand alone. For this Dr Darwin assigns two causes; 1*st*, That the young of some animals come into the world in a more complete state than those of others; the colt and lamb, for example, enjoying, in this respect, a striking advantage over the puppy and the rabbit. 2*d*, That the mode of walking of some animals coincides more perfectly than that of others with the previous motions of the *fœtus in utero*. The struggles of all animals, he observes, in the womb must resemble their manner of swimming, as by this kind of motion they can best change their attitude in water. But the swimming of the calf and of the chicken resembles their ordinary movements on the ground, which they have thus learned in part to execute while concealed from our observation; whereas the swimming of the human infant, differing totally from his manner of walking, he has no opportunity of acquiring the last of these arts till he is exposed to our view. The theory is plausible, and does honour to the author's sagacity; but, as I observed in a former instance, it only places in a new light that provident care which Nature has taken of all her offspring in the infancy of their existence.

"Another instance may contribute towards a more ample illustration of the same subject. A lamb, not many minutes after it is dropped, proceeds to search for its nourishment in that spot where alone it is to be found, applying both its limbs and its eyes to their respective offices. The peasant observes the fact, and gives the name of *instinct*, or some corresponding term, to the unknown principle by which the animal is guided. On a more accurate examination of circumstances, the philosopher finds reason to conclude, that it is by the sense of *smelling* it is thus directed to its object. In proof of this, among other curious facts, the following has been quoted: 'On dissecting,' says Galen, 'a goat with young, I found a brisk *embryon*, and having detached it from the *matrix*, and snatched it away before it saw its dam, I brought it into a room, where there were many vessels, some filled with wine, others with oil, some with honey, others with milk, or some other liquor, and in others there were grains and fruits. We first observed the young animal get upon its feet and walk; then it shook itself, and afterwards scratched its side with one of its feet; then we saw it smelling to every one of those things that were set in the room, and when it had smelt to them all, it drank up the milk.'[2] Admitting this very beautiful story to be true, (and, for my own part, I am far from being disposed to question its probability), it only enables us to state the fact with a little more precision, in consequence of our having ascertained that it is to the sense of smelling the instinctive determination is attached. The conclusion of the peasant is not here at variance with that of the philosopher. It differs only in this, that he expresses himself in those general terms which are suited to his ignorance of the particular process by which nature in this case accomplishes her end; and if he did otherwise, he would be censurable for prejudging a question of which he is incompetent to form an accurate opinion. A person who is totally unacquainted with anatomy, may nevertheless admire (and may admire on as good grounds as Cuvier himself) the mechanism of the human hand, or of the elephant's proboscis.

"The foregoing observations on the instincts of the new-born kid are strictly applicable to the attempts which have been made to account for the instincts of migratory birds and fishes, by changes in their sensations produced by the vicissitudes of the seasons. Of these attempts I have met with none which seem to me at all satisfactory; at the same time I have no doubt that it is by some physical means that the effect is accomplished, and I think it highly probable that new lights will be thrown on the subject by the researches of future naturalists.[3] But whatever success may attend their inquiries, the provident arrangements thus made for the preservation of animals must still be referred, not to their own foresight and sagacity, but to the wisdom and beneficence of Nature; and the questions so nobly and philosophically expressed by the poet will still remain, and, we may venture to predict, will for ever remain (as to their essential import) in all their force.

'Who bade the stork Columbus-like explore
Heavens not his own, and worlds unknown before?

[1] "*Biographical Memoirs of Smith, Robertson, and Reid*, p. 475. From the last of these Memoirs several of the following paragraphs are transcribed."

[2] *Darwin*, vol. i. pp. 195, 196.

[3] "From some observations made by Dr Jenner, in prosecution of a suggestion thrown out by the celebrated John Hunter, it seems now to be completely established, that, in the case of migrating birds, the inciting causes of migration are certain periodical changes in the testes and ovaria of the male and female.

"The fact is extremely curious, but offers no explanation whatever of the grand problem: it may account for the bird's restlessness and desire to change its abode; but the same difficulty still recurs, and only meets us in a new form. How are we to explain the invariable flights of the bird towards a particular *unknown* region? For it must not be forgotten that its migrating instinct has at once a reference to a period of the season in the country which it leaves, and to that in the country for which it is bound. Of this I have no doubt that both these ingenious authors were fully aware. (*Observations on the Migration of Birds*, by Edward Jenner, M.D. F.R.S. *Philosophical Transactions of the Royal Society of London* for the year 1824, Part I. See also the late Mr John Hunter's *Observations on certain parts of the Animal Economy*.)"

Who calls the council, states the certain day,
Who forms the phalanx, and who points the way?'[1]

The sophistry which runs through Darwin's reasonings concerning instinct, is partly owing to the unauthorized and arbitrary meaning which he has annexed to that word.

"'By a due attention to these circumstances,' he observes, 'many of the actions of young animals which, at first sight, seemed only referable to an inexplicable instinct, will appear to have been acquired, like all other animal actions that are attended with consciousness, *by the repeated efforts of our muscles, under the conduct of our sensations or desires*.'[2]

"Our sensations and desires (it is to be observed) are admitted by Darwin 'to constitute a part of our system, as our muscles and bones constitute another part; and hence,' says he, 'they may alike be termed *natural* or *connate*, but neither of them can properly be termed *instinctive*, as the word *instinct*, in its usual acceptation, refers only to the *actions* of animals. The reader,' continues Darwin, 'is intreated carefully to attend to this definition of *instinctive action*, lest by using the word *instinct* without adjoining any accurate idea to it, he may include the natural desires of love and nunger, and the natural sensations of pain and pleasure under this general term.'[3]

"According to this explanation, the difference of opinion between Dr Darwin and his opponents is chiefly verbal; for whether we consider the actions of animals commonly referred to *instinct*, as the immediate result of implanted determinations, or as the result of *sensations and desires* which are *natural or connate*, they afford equally manifestations of design and wisdom in the Author of their being, inasmuch as, on both suppositions, they depend on causes either mediately or immediately subservient to the preservation of the creatures to which they belong. On both suppositions, there is an infallible provision and preparation made by the hand of Nature for the effect which she has in view.

"I was glad to find that the same remark on this part of Darwin's theory had been previously made by Dr Paley. 'I am not ignorant,' says he, 'of the theory which resolves instinet into sensation. . . . Thus the incubation of eggs is accounted for by the pleasure which the bird is supposed to reeeive from the pressure of the smooth convex surface of the shells against the *abdomen*, or by the relief which the mild temperature of the egg may afford to the heat of the lower part of the body, which is observed *at this time* to be increased beyond its usual state. . . . In this way of considering the subject, sensation supplies the place of foresight; but this is the effect of foresight on the part of the Creator. Let it be allowed, for example, that the hen is induced to brood on her eggs by the enjoyment or relief which, in the heated state of her *abdomen*, she experiences from the pressure of smooth round surfaces, or from the application of a temperate warmth. How comes this extraordinary heat or itching, or call it what you will, which you suppose to be the cause of the bird's inclination, to be felt just at the time when the inclination itself is wanted, when it tallies so exactly with the internal constitution of the egg, and with the help which that constitution requires in order to bring it to maturity? In my opinion this solution, if it be accepted as to the fact, ought to increase, rather than otherwise, our admiration of the contrivance.'"

INSTITUTES, a book containing the elements of the Roman law. See CIVIL LAW.

National INSTITUTE of France, was founded by a decree of the new constitution, and opened on the 7th of December 1795. The abolition of royalty naturally suggested to the democratic rulers of France, that it would likewise be proper to abolish every thing which had the remotest connexion with it. Condorcet therefore proposed that the seven old academies, which had the term *royal* prefixed to them, should give way to the establishment of one new academy of arts and sciences, under the title of the *National Institute*.

The Academy, or Institute, was to consist of two hundred and eighty-eight members, the half of whom were to have their residence in Paris, and the rest in the different departments, with twenty-four foreign members.

This academy was divided into three classes; these were subdivided into sections, and each of these again consisted of twelve members. The *first class*, consisting of ten sections, were to preside over mathematics, mechanical arts, astronomy, experimental philosophy, chemistry, natural history, botany, anatomy and animal history, medicine and surgery, animal economy, and the veterinary science. The *second class*, having for its department morality and politics, consisted of six sections, viz. analysis of sensations and ideas, morals, legislature, political economy, history, and geography. The *third class*, consisting of eight sections, presided over literature and the fine arts, viz. universal grammar, ancient languages, poetry, antiquities, painting, sculpture, architecture, and music. Several volumes of memoirs have been published by each of the classes.

The Institute was new-modelled by Napoleon in 1806, and again on the return of the Bourbons. By a decree of the 21st of March 1816, it was ordered that the Institute should be composed of four academies; viz. the French Academy, the Royal Academy of Inscriptions and Belles Lettres, the Royal Academy of Scienees, and the Royal Academy of Fine Arts. Some alterations were at the same time made in the number of members, and in other particulars.

INSTITUTION, in general, signifies the establishing or founding of something. In the canon and common law, it signifies the investing a clerk with the spiritualities of a rectory or other preferment, which is done by the bishop, who uses the following formula: "I institute you rector of such a church with the cure of souls, and receive your care and mine."

INSTITUTIONS, in literary matters, denote a system of elements or rules of any art or science. Thus physical or medical institutions are such as teach the *præcognita* necessary to the praetice of medicine, or to the cure of diseases.

INSTRUMENT, in general, whatever is subservient to a cause in producing any effect.

INSTRUMENT is also used in law to signify some public act, or authentic deed, by means of whieh any truth is made apparent, or any right or title established, in a court of justice.

[3] *Zoonomia*, vol. i. p. 188, third edition corrected, 1801.

"Were this very arbitrary limitation of the word *Instinct* adopted, we should be forced to reject as improper, the employment of that term in the passage formerly quoted from Mr Smith, in which he speaks of the *instinctive perception* of distance from the eye in certain classes of animals. The same use of the word occurs in various other parts of his works. 'There seems,' he observes on one occasion, 'to be in young children an *instinctive* disposition to believe whatever they are told.' And a few pages afterwards, 'The desire of being believed, the desire of persuading, leading, and directing other people, seems to be the strongest of all our natural desires. It is perhaps the *instinct* upon which is founded the faculty of speech, the characteristical faculty of human nature.' (*Theory of Moral Sentiments*, vol. ii. pp. 382, 384, sixth edition.) As an authority for the *usual acceptation* of a philosophical term, Mr Smith will be allowed to rank somewhat higher than Dr Darwin."

INSURANCE.

Insurance. INSURANCE is a contract of indemnity, by which one party engages, for a stipulated sum, to insure another against a risk to which he is exposed. It is of three kinds, viz. Fire, Life, and Marine; all of them producing similar results by very different means. The party who undertakes the risk is called the insurer, assurer, or underwriter, and the party protected by the insurance is called the insured or assured; the sum paid is called the premium, and the instrument containing the contract is termed the policy.

I.—FIRE INSURANCE.

Fire insurance. This species of insurance has been practised in Great Britain for nearly a century and a half, and is now, notwithstanding the heavy duty imposed upon it, of almost universal use, particularly in our cities and large country towns. Though practised in France, Holland, Austria, and other countries on the Continent, it is not general anywhere except in Great Britain; and in this country fire insurance is not confined to subjects within the realm, or even to our colonies, but is extended to risks of all descriptions, and in every quarter of the world. Indeed, of late years foreign fire insurance has become a most important addition to the extensive transactions of some of the principal London establishments, a very considerable portion of their premiums being derived from insurances effected in other countries.

Insurance against fire is that contract by which the insurer, in consideration of a certain premium received by him, undertakes to indemnify the insured against all losses or damage which he may sustain by fire, within a limited period, in his houses, warehouses, merchandise, or other property. Insurances of this description are generally made by joint-stock companies, of which the principal are in London, though there are now several in almost all the large towns throughout the kingdom; and there is scarcely a village in which there are not some of their branches and agents. Most of these insure at their own risk, and for their own profit; in a few of them, however, called contribution societies, every person insured becomes a proprietor, and participates in the profit or loss of the concern.

The only society of this description in Scotland is the Friendly Insurance Incorporation, which was also the first established company in this part of the island for insurance against loss by fire. In 1720 there had been some disastrous fires in Edinburgh, by which many individuals sustained great loss of property; and in the same year a meeting of inhabitants took place, for the purpose of founding a society for their mutual protection from loss in cases of fire. A certain per-centage of premium upon the sum insured by each proprietor or contributor was paid for a perpetual insurance on their properties, and these premiums formed the capital stock of the concern. The corporation, however, much more than answered the purpose which those interested in its formation had in view; for, after the payment of all claims for loss, the capital, by judicious management, had accumulated to such an extent, that in 1760 it was resolved no longer to limit the business to Edinburgh and Leith, but to extend it over Scotland, and upon every description of property, on the principles now followed by other insurance companies.

The rules by which these establishments are governed, and the conditions on which they insure, are made by their own directors; and as a copy of these conditions is printed upon the policy, and forms a part of the contract therein contained, the insured is understood, by his acquiescence, to submit to their proposals, and is fully apprized of those rules, upon the compliance or non-compliance with which, he will or will not be entitled to an indemnity.

Fire Insurance.

Laws. The construction to be put upon the regulations of the various offices has but seldom become the subject of judicial inquiry; and the law of the case, in as far as it has been ascertained by precedent, is of course embraced by all of them.

1. The insurers must be made fully acquainted with the nature of the risk they are required to cover. Any misrepresentation in describing the building or goods, or the process of manufacture carried on, whereby the same may be charged at a lower rate of premium than they would otherwise be, invalidates the policy; and if any alteration be made in the state of the building or process of manufacture after the insurance is effected, the insured is required to give due notice thereof to the insurers, as, in default, he will be unable to recover under his policy. Concealment, too, is not less fatal to the contract than positive misrepresentation. A policy was effected at the Phœnix Fire Office on the 25th of July 1814, "on a warehouse in the lower town of Heligoland, for three months, as by letter of 11th July 1814." It appeared that the person applying for insurance had two warehouses in Heligoland, one of them separated by another building from a boat-builder's workshop, in which a fire broke out at seven in the evening of the 11th July, but apparently was almost immediately extinguished. The same evening after this had occurred, the insured wrote to London for a three months' insurance of L.400 on the warehouse near the boat-builder's, and L.3500 on coffee therein. The mail was shut; but the master of the packet took the letter to Cuxhaven, and there put it into the post-office. The insurance was effected without any disclosure of what had happened. Early in the morning of the 13th a fire again broke out in the boat-builder's, and destroyed the adjoining warehouse, with its contents. The jury, though they acquitted the plaintiff of any fraudulent intention, thought that the fire of the 11th ought to have been communicated, and therefore found for the defendant. Bufe *v.* Turner, 1814.

2. Nothing can be recovered from the insurers in the event of loss, unless the party insuring had an interest or property in the thing insured at the time when the insurance was effected, and when the loss happened. Any trustee, mortgagee, reversioner, factor, or agent, however, has sufficient interest in the goods under his custody to effect a policy of insurance, provided the nature of such interest be distinctly specified at the time of executing such policy. In the same manner, it is customary for hotel and inn-keepers to insure the property of their lodgers; of the masters of boarding-houses to insure that of their scholars; of salesmen and auctioneers to insure merchandise, furniture, &c. whilst about to be disposed of in their premises; and so forth.

There is reason to believe that frequent frauds are perpetrated by individuals insuring to a large amount property of trifling value; and it is an undoubted fact that fraudulent and excessive claims are of constant occurrence. These have been very much increased by the competition and keenness for business which have existed amongst the offices for some years past. But parties are not always aware, that in tendering such a claim, they are running the risk of *forfeiting all right under their policy.* This was decided in 1832 in the case of Friedlander *v.* the London Assurance Company, where, although it was not denied that loss and damage had been occasioned by fire, and that not arising from improper means, still, from the extravagance of the claim made by the pursuer, it was held to be a fraudulent valuation, and a verdict was consequently given against him. No reliance can be placed on the oath of a suspected claimant; if a man make out a fraudulent claim, he will not be very scrupulous in swearing to its correctness.

On the other hand, where a loss has occurred, and there is no suspicion of any unfair practice on the part of the insured, it is the duty of the insurers to be generous and liberal. The insured is always put to much inconvenience, and frequently to serious loss beyond what he can claim for under his policy; and therefore a fair sufferer ought to be promptly and cheerfully settled with.

3. In general there is an exception in favour of the insurers in cases of fire occasioned by "invasion, foreign enemy, civil commotion, riot, or any military or usurped power whatever." The terms "civil commotion and riot" were introduced in consequence of its having been found that the term "usurped power" means an invasion from abroad, or an internal rebellion, not the power of a common mob. The offices likewise, with propriety, decline paying losses on hay or corn occasioned by spontaneous combustion, though they make good the loss of any other property in consequence of such fire; it being the interest of the community at large to put down all such occasions of loss as are contained in the former, and negligence generally being the cause that damage is sustained in the latter. The offices, however, pay all loss by fire occasioned by lightning, as well as, *primo loco*, all losses caused by incendiarism, though in this last case they have a claim on the county for indemnification.

4. "Books of accounts, written securities, bills, bonds, tallies, and ready money," are naturally not the proper subjects of insurance, and are therefore excepted by all the offices; many adding to this list "gunpowder."

5. China, glass, crockery, and mirrors, are usually made the subject of a distinct item in a policy of insurance; and, from their fragile nature, are always charged as doubly hazardous. The rate for "curiosities" is the same. Pictures and prints are generally taken at single hazardous; but when a very valuable collection is insured, the offices usually require a catalogue, with a distinct value attached to each. Jewels, trinkets, mathematical and musical instruments, are by some offices also required to be valued separately, and in that case are charged single hazardous. Generally, however, these are considered as common risks, and are included along with printed books, linen, and liquors, in one item with "household furniture."

6. It often occurs that no one office will insure to the full amount required by an individual who has large property; and in such cases the party, to cover his whole interest, is obliged to insure at different offices. But in order to prevent the frauds that might be practised by insuring the full value in various offices, there is, in the proposals issued by all the companies, an article which declares that persons insuring must give notice of any other insurance made on their behalf elsewhere upon the same houses or goods, that the same may be specified and allowed by indorsement on the policy, in order that each office may bear its rateable proportion of any loss that may happen; and unless such notice be given of each insurance to the office where another insurance is made on the same effects, the insurance made without such notice will be void. Different people, however, may have different interests in the same property, and each may insure his own interest without communication with the others.

7. An important condition in the proposals is that referring to the proof of loss. Most offices make it a condition that the individual claiming shall procure a certificate under the hands of some reputable householders, and minister of the parish, to the satisfaction of the company, importing that they are acquainted with the character and circumstances of the person insured, and do know, or verily believe, that he really, and by misfortune, without any kind of fraud or evil practice, has sustained, by such fire, loss and damage to the amount therein mentioned. This condition has given rise to a great deal of discussion in the courts; but it has been finally settled, that the procuring of the certificate is a condition *precedent* to the payment of any loss, and that its being wrongfully refused will not excuse the want of it.

8. On bespeaking policies, the insured are required either to pay the premium, or make a deposit for the same; the Phœnix and most other offices conditioning, that unless an interim-receipt for such payment has been issued, either by the office or one of its agents, no order for insurance shall be held as in force. Fifteen days are allowed at the expiration of each year for the payment of the premium for the next year in succession, upon all annual policies, and others for a longer period; and, provided the premium be paid within that time, the insured is considered as under the protection of the office. But the Phœnix and other offices always expressly declare, in all policies for a shorter period than a year, that the insurance ceases at six o'clock in the evening of the day mentioned therein. If, however, either the insurers or the insured intimate, during the continuance of a policy, their intention of dropping the contract at the expiration of the year, it has been decided, that a loss happening within the fifteen days after the end of the year does not in such a case fall under the contract.

9. A policy of insurance is not in its nature assignable, nor can it in England be transferred without the express consent of the office. In Scotland every pecuniary obligation is assignable; but there being something of the nature of a *delectus personæ* in this contract, the power of assignment is, by the terms of the policy, put under particular restraints. When, however, any person dies, his interest remains in his executors or administrators respectively, who succeed or become entitled to the property, provided such representatives procure their right to be indorsed on the policy. In the same way, no one who sustains a loss on stock or merchandise in premises to which he has removed since his policy was extended, has a valid claim, if such change be not indorsed on the policy in question. On bankruptcy the creditors are entitled to the full benefit of the policy, provided the premium has been duly paid up.

10. The insurers are liable, not only for loss by burning, but for all damage or injury caused by the accident, as well as for all reasonable charges attending the removal of articles which may never have been touched by the fire; as, for instance, in the case of the gable of a house falling across a street, and damaging the property on the opposite side, or in the case of destruction done to fine goods by the smoke of a conflagration in the vicinity, or from the water which may have been thrown about in endeavouring to extinguish it. In such cases the insurers are distinctly liable; but as their contract is one of indemnification only "for loss or damage by fire," there must have been actual ignition to entitle the insured to recover, it not being sufficient that there has been a great and injurious increase of heat, whilst nothing has taken fire which ought not to be on fire. For example, in one case of a sugar-house, in which, for the purposes of the manufacture, heat was communicated to each of the separate stories by a chimney, forming nearly one side of the house, at the top of which there was a register; the neglect to open this register on one occasion caused an excessive heat, which blackened the walls, and injured the sugar in different states of preparation; but the damage thus sustained was held not to come under the spirit of the contract.

11. The loss by fire is scarcely ever a total loss, and the valuation in the policy is only the fixing of a maximum, be-

yond which the underwriters are not to be liable, and not the conclusive ascertainment of the value to be replaced. There is no such thing in this contract as the "average" in marine insurance; the amount insured is payable to its full extent, without (unless otherwise stipulated) any reference to the value of the subject insured, either in itself, or in comparison with such parts of it as have been saved; at least such is the practice in Great Britain, but on the Continent all policies are subject to average. The loss is generally settled by arbitration, and a clause of reference is consequently inserted in most policies. The company, however, generally retain the right of either reinstating the subject lost or damaged, or of paying its value.

Insurances are generally divided into *common*, *hazardous*, *double hazardous*, and *special*. The charge for insuring property of the first description is now usually 1s. 6d. per cent., the second 2s. 6d., the third 4s. 6d., whilst the fourth, as its name denotes, comprehends those extra risks which are made the subject of special agreement between the parties.

It is almost impossible to form a correct classification of the risks comprehended under these heads, as the higher risks not only vary most materially in themselves, but in one large town it is well known that losses are constantly occurring upon a species of risk which in another is rarely or never the cause of a fire. But as the law of average is a fundamental principle in insurance, and can only be derived from observations made on a very large scale, the tables published by most offices are formed principally from experience.

The table of minimum premiums agreed to by several of the Scotch offices in 1830 is as follows:

Premium per cent.	s.	d.
Apothecaries	4	6
Bookbinders	5	0
Booksellers	2	0
Cart or wheel-wrights, without stove	5	0
Ditto with stove	10	6
Calenderers	3	0
Ditto with steam-engine	4	6
Cotton-mills	14	0
Cotton wool	2	6
Corn-mills without kiln	7	6
Ditto with kiln	10	6
Distilleries with or without kiln, and all communicating therewith	10	6
Farm-stocking.		
Farm dwelling-house, slated or tiled, and detached from offices	2	0
Farm dwelling-house thatched	5	0
Slated or tiled offices	2	6
Thatched ditto	5	0
Stock in barn-yard, for the year	2	6
Ditto in ditto for shorter period	2	0
Ditto within risk of steam-engine	4	6
Flax-mills, warranted no carding of tow or heckling therein	16	0
Ditto with carding of tow	18	0
Ditto with the addition of heckling	20	0
Hotels and taverns	2	6
Hecklers, without artificial light	5	0
Ditto lighted from without	7	6
Ditto lighted from within	10	6
Jewellers, stock generally	3	0
Or, if divided, thus:—		
Plate and plated goods and cutlery	2	0
Stock of jewellery	4	6
Mansion-houses	2	0
Muslin goods in warehouse	2	0
Printers	5	0
Paper-mills heated by steam, no stove	5	0
Ditto with stoves having flues	21	0
Public libraries	2	0
Pawnbrokers	5	0
Power-loom factories	5	0
Retail spirit-dealers	2	6
Soap manufacturers	3	0
Ditto with steam-engine	4	6
Sugar-refiners.		
Old refinery, building	31	6
Stock and utensils	42	0
If any cockle, not covered with a brick arch, but only protected by a tile or metal covering, 5s. per cent. extra, for building and stock.		
Steam process only, building	16	0
Stock and utensils	21	0
Mixed process, building	25	0
Stock and utensils	31	6
Theatres, Edinburgh and Glasgow	31	6
Woollen-mills without stove	7	6
Ditto having one or two stoves	10	6
three or four stoves	12	6
five or more stoves	15	0
Wrights, house-carpenters, or cabinet-makers, without stove	10	6
With stove	15	0

The statute 55 Geo. III. c. 184, imposes on every policy a duty of one shilling, and also the annual sum of three shillings for every L.100 insured for a year, and according to that rate for any fractional part of L.100 insured, and for any fractional part of a year.

All property excepting farm stock and public hospitals is liable to this duty. It is collected by the offices along with their premiums, and they are allowed a drawback of five per cent. upon it for their trouble and expense in so doing. From the last returns, it appears that this duty amounts to nearly L.900,000 per annum, which shows that British property to the extent of at least six hundred millions sterling must be covered by our insurance offices.

This, however, affords no criterion of the actual amount of risk undertaken by these offices. In the first place, because the duty on farm-stock having been repealed in 1833, that very extensive description of risk is not included in this calculation; and, secondly, because some of the offices underwrite foreign risks to a very large amount, and these are equally, by act of parliament, exempt from duty. Perhaps, therefore, the enormous sum of one thousand millions sterling does not greatly exceed the amount of property insured by our British fire establishments.

The advantages of fire insurance are too prominent to require any description here. It affords great comfort to individuals, and often preserves whole families from poverty and ruin. The destruction of a mansion-house, or the conflagration of a cotton-mill, is a calamity that would press heavily on even the richest. But when distributed amongst several individuals, each feels it proportionally less; and provided the number of those amongst whom it is distributed be very considerable, it occasions no sensible inconvenience to any one in particular. Hence the advantage of combining to lessen the injury arising from the accidental destruction of property; and it is the diffusion of the risk of loss over a wide surface, and its valuation, that forms the employment of those engaged in the business.

II. LIFE ASSURANCE.

The insurance, or assurance on lives, as it is now most generally termed, is the insurance of a certain sum of money to be paid in the event of a person named being alive at a certain time, or dying within a certain time, or to be paid within a certain time after the death of a person named, whenever that may happen.

Life assurance is comparatively of recent date in this country; for, although the Amicable Society was incorporated by charter as early as the reign of Queen Anne, it was not till the commencement of the present century that its beneficial effects came to be felt, and that as a business it was carried to so great an extent. The precarious dependence of a numerous family upon the life of a single person naturally induces the desire of seeking some protection against a calamity which, sooner or later, must befall them; and this, probably, suggested the first idea of insurances upon lives, as an expedient by which a pecuniary indemnity, at least, might be secured to the sufferers, sufficient to rescue them from the poverty and distress which otherwise awaited them. All professional persons, or those living on salaries or wages, such as lawyers, physicians, military and naval officers, clerks in public or private offices, &c., whose incomes must of course terminate with their lives, and many others who are either not possessed of capital, or cannot dispose of their capital at pleasure, must naturally be desirous of providing, as far as they may be able, for the comfortable subsistence of their families in the event of their death. Take, for example, a physician or lawyer, without fortune, but making perhaps L.1000 or L.2000 a year by his business, and suppose that he marries and has a family. If this individual attain to the average duration of human life, he may accumulate such a fortune as will provide for the adequate support of his family at his death. But who can presume to say that such will be the case; that he will not form one of the many exceptions to the general rule? And suppose that he were hurried into an untimely grave, his family would necessarily be destitute. Now it is against such calamitous contingencies that life assurance is intended to provide. An individual possessed of an income terminating at his death, agrees to pay a certain sum annually to an insurance office; and this office binds itself to pay to his family, at his death, a sum equivalent (under deduction of the expenses of management and the profits of the insurers) to what these annual contributions, accumulated at compound interest, would amount to, supposing the insured to reach the common and average term of human life. Though he were to die the day after the insurance was effected, his family would be as amply provided for, as it is likely they would be by his accumulations, were his life of the ordinary duration. In all cases, indeed, in which those insured die before attaining an average age, their gain is obvious. But even in those cases in which their lives are prolonged beyond the ordinary term, they are not losers; they then merely pay for security which they could not otherwise have possessed. During the whole period from the time when they effect their insurances, down to the time when they arrive at the mean duration of human life, they are protected against the risk of dying without leaving their families sufficiently provided for; and the sum which they pay after having passed this mean term, is nothing more than a fair compensation for the security they previously enjoyed.[1] To heirs of entail, clergymen, professional men, men in trade and business, and generally to all liferenters, life insurance is therefore peculiarly suited. By the same means also facilities are afforded for raising money on loan, creditors may in many cases obtain ultimate payment of their debts, and provisions in marriage settlements are secured.

Policies of this kind are most frequently granted by companies, on account of the greater security there is in large bodies of men, than it is easily possible to be attained by an individual when the policy may be of long continuance.

The premium of assurance is either a gross sum paid at once, or a sum paid down on the day that the contract is made, with an obligation to pay the same sum annually during the existence of the policy. The latter is the more general mode of assurance.

When a party is desirous of effecting an assurance, he receives from the office of the company a printed paper called a declaration, which he fills up with the name of the party to be assured, his age, the place and time of his birth, and place of his present residence, with certain particulars as to his health. To corroborate the statement, references are given to two or more persons well acquainted with the party, one of whom must be a medical man. The reasons for these precautions are obvious.

When the declaration has been thus completed, the person by whom the assurance is made makes his appearance at the office of the company, where he is interrogated as to the general state of his health, and a minute is entered in their books accordingly. The letter of the referees, with the declaration, are subsequently laid before the directors, who, from these documents, and information frequently derived from other sources, form their decision. On the payment of the premium a receipt is given, containing the number of the policy, which is then made out according to the declaration, signed by a certain number of directors, and delivered to the other party interested in it. If the person on whose life the assurance is made cannot appear before the directors, or any one appointed by them for that purpose, an additional sum is frequently charged for non-appearance. There is also a duty to be paid to government on each policy, in addition to the first year's premium; but the premium only is named in the policy, as on the future payment of this sum its existence depends.

A policy is assignable, and frequently forms a security for sums advanced, and not unfrequently becomes an object of sale. In these cases the holder of the policy pays the future premiums, and the advantage of a purchaser consists in holding a policy at a less premium than he must have paid at the present age of the party on whose life the assurance was made. Thus, supposing a policy to have been granted for the payment of L.1000 at the death of a party aged between thirty and thirty-one when the policy was made; if sold when the party is between fifty and fifty-one, the purchaser will have to pay L.26. 2s. 6d. annually during the existence of the policy; whereas, if he had taken out a policy at the present age of the party, his premium would be L.45. 11s. 8d.; and for the difference between these two sums, namely, L.19. 9s. 2d., a price is fixed on. The public sale of a policy, however, possesses this disadvantage, that the bidders are frequently unacquainted with the person on whose life the assurance is made; and, being liable to trouble and expense, to ascertain that he is alive at each payment of the premium, must require a deduction on this account, from what they might otherwise presume to be a compensation for the difference between the two premiums. Policies are in consequence sold at very disproportionate prices; and it is evident, that a policy must be most valuable to the party insured, and less so to others, according to their convenience of paying the premiums, and receiving proper information respecting the party in whose life and death they are interested.

On the death of the party on whom the claim depends, certain documents are required, such as the register of the burial of the deceased, and references to the medical persons or others who attended him in his last illness; and, if he effected the policy himself, the probate of his will, or, if it has been assigned to another, a copy of the assignment. The nature of his death must also be ascertained; as, in ease of any contravention of the conditions of assurance, the policy is vitiated. In the interval between the notice of the party's death, and the time assigned for the payment of the claim, which by most of the offices is fixed at three months, due investigation is made, and, every thing being found satisfactory, the claimant brings with him the policy, and a receipt for the sum claimed, which is immediately paid.

When a claim is payable in the event of a person being alive at a certain time, his appearance before the directors is requisite, or sufficient proof must be given that he was alive at the time defined by the policy. Policies de-

[1] See M'Culloch's *Commercial Dictionary*, art. *Insurance*.

Life Assurance.

pending on a person being alive at a certain time are very rare, and chiefly confined to endowments for children, in which case the payment of a gross sum down, or of an annual payment till the child attains the age of 14 or 21, secures to that child, at that age, the sum named in the policy.

For adjusting the premium to be paid according to the age of the party on whom the assurance is made, tables of rates have been formed, and those derived from the registers of mortality at Northampton and Carlisle are in general adopted. Tables of the duration of human life have also been made from observations in various other places; amongst which the most distinguished are those of De Parcieux, Kerseboom, Aikin, the registers of Sweden, Finland, and London; and one published within these few years by the Equitable Society, founded on the experience of that well-known establishment.

In the formation of these tables, a vulgar error is entertained, that they are dependent on chance; for life being uncertain, every attempt to regulate premiums is of no avail. It is true that life cannot be reduced to a certain scale, that is, if a thousand persons are named, it is impossible to state how many will die in each year, till the whole cease to exist. But if the observations are extended over a very large surface, and very numerous data are collected, the most accurate calculations may be made of the *probable* duration of any one life.

After a scale of life has been adopted, a table of premiums is derived from it by strict mathematical calculation, and in a very ingenious manner. Suppose the premium for a person of a certain age to be known, then the premium for a person of one year younger, being compounded of the premium for one year and the present value of the above premium, is easily calculated from the table of lives. The rule is this: Multiply the premium on the oldest life into the number of persons alive in the tables of that age, and divide by the number of persons of the younger age alive in the tables. This sum discounted for a year gives the premium for assuring the desired sum at the end of the year. Then multiply the sum to be assured into the number of persons of the younger age that die according to the tables in a year, and divide by the number of persons alive at that age, and this sum discounted for a year is the assurance of the sum for the first year, and, consequently, the two sums added together give the desired premium. Now, as the oldest person in the scale of life dies in the ensuing year, the premium on him is evidently the sum to be paid discounted for one year, and thence the premium for the age below is ascertained by the above rule; and so of every age in succession. No errors can be committed without detection, as every step is checked by a similar table drawn out for the value of an annuity at each age.

In a similar manner, tables are formed for the assurance of a sum payable at the death of one out of two persons, or at the death of the survivor of two persons, or at the death of one on the contingency of his surviving another, and so on.

The above rules give tables of rates for the payment of a gross premium; but as it is generally more convenient to pay an annual sum equivalent to it, a table of rates is made for this case, and it is formed by dividing the gross premium by the value of an annuity upon each age added to unity. If the annual premium were paid at the end of the year, the addition of unity would be unnecessary; but a policy is not granted till one premium is paid, and hence the necessity of the addition is obvious.

As premiums are settled from a fixed table of observations on life, it is evident that, as deaths never happen exactly in the order prescribed in the tables, there must arise either a surplus or deficiency of capital for the payment of the sums assured. From the care which has hitherto been taken in the choice of lives, and the high premium which the offices have been enabled to demand, all the old establishments have accumulated very large capitals; consequently, we believe it has never occurred that the proprietors have been called upon to make up a deficiency. It is in the management of this capital, or surplus, that life assurance companies differ. One of them, termed Proprietary Companies, undertake to pay *fixed* sums upon the death of the individual assuring with them; the profits made by such companies being wholly divided amongst the proprietors, their premiums are generally, or at least ought to be, lower than those of others. Of this class are the Pelican, Sun, and others, principally of old standing. The second class of life assurance companies are the Participating, which, instead of undertaking, like the former, to pay certain specified sums upon the death of the assured, allow the latter to participate, to a certain degree, along with the proprietors, in the profits made by the business. The mode in which this class allot their profits is not the same in all, as we shall immediately see; but in general their premiums are somewhat higher than those of the preceding, and are made to depend in a considerable degree on the amount of the profits set apart for the insurers. The Alliance, Guardian, and Rock, as well as a large portion of the new companies, are of this description; and latterly a considerable number of them have united their participating with their proprietary business, by publishing different scales of premiums to suit the wishes and intentions of individuals assuring. The third class are Mutual Assurance Companies, of which the Equitable of London is the groundwork and model. In this sort of company there is no proprietary body distinct from the assured. The latter, after deducting the expense of management, share amongst themselves the whole profits of the concern; and therefore, as all the surplus returns to themselves, their scales of premiums are naturally higher than that of either of the foregoing.

In the two last classes, where the surplus is made advantageous to the assured, either a sum is at certain periods added to each policy, or the premium is diminished. In both cases, a valuation is made of all the annual premiums, with the past and future expected accumulations, and also of the claims upon every policy. It is requisite, however, that the utmost care should be taken to secure to each policy the sum named in it, with every addition made to it; and hence a certain portion, generally a third or a fifth, of the surplus is constantly retained to guard against possible contingencies. This reservation occasions a singular anomaly in mutual assurance companies. In these all are partners, being guarantees to one another for the payment of their respective claims. The surplus arising from the excess of premiums, with their accumulations above the claims, evidently belongs to the whole of the company, and consequently each partner is entitled to a portion of it. But of this surplus, a third or fifth being constantly reserved, and each person at his death ceasing to be a partner, every person leaves behind him a portion for his successors. The third or fifth is therefore, we may say, without an owner; for a partner has not a right to it during his life, and his heirs or assignees have not a claim to it after his death.

Policies of life assurance must be on stamped paper, the duty being as follows:

Where the sum in the policy does not exceed L.50	L.0	2	6
L.50, but not exceeding L.100	0	5	0
Where it does not amount to L.500	1	0	0
Where it amounts to L.500 and not to L.1000	2	0	0
...1000 3000	3	0	0
...3000 5000	4	0	0
...5000 and upwards	5	0	0

The premiums required by the principal offices are exhibited in the following tables.

Age.	Amicable, Scot. Equitable, Widows' Fund.	Metropolitan.	Norwich Union.	Equitable.

Many of the offices have tables calculated for special purposes; so that, in one or other of them, any individual wishing to effect an assurance is certain of having it done in the way he desires. For instance, the Pelican, amongst others, has a table of "Limited Payments," by which persons desirous of paying an annual premium for a limited number of years, instead of one to continue annually during life, may do so on the following terms.

Age.	Payable for Five Years.	Payable for Seven Years.	Payable for Ten Years.	Payable for Fifteen Years.
15	£6 19 4	£5 4 0	£3 17 8	£2 17 6
16	7 2 2	5 6 1	3 19 3	2 18 8

10	63 15 6	7 0 4

The advantage to a person assuring in any one office as compared with another, must plainly depend on a comparison between the premiums demanded, the conditions of the policy, and, above all, the security which it holds out. Where it is wished to assure on a certain life for a limited period, the party having no interest in procuring a larger sum, in case of death, than the amount assured, makes his application to that office where he can get it effected at the lowest premium. Such an office will be a Proprietary one. The principal advantage of such companies is, that individuals dealing with them know exactly what they are about. They know the precise premium they will have to pay, and the exact amount of the sums that will accrue to their assignees at their decease. The subscribed capital of such associations as the Pelican, Sun, Royal Exchange, &c. and the wealth of their partners, afford unquestionable security; and, unless some very unprecedented and unlooked-for change in the condition of the country take place, they may reckon with certainty on the terms of the policy being fulfilled to the letter. If, on the other hand, the individual be desirous of leaving as large an amount as he can afford to assure to his family, and more especially if he happen to be a young and a healthy life, he will generally prefer the conditions of a Participating or a Mutual Assurance society. The subscribed capital and fortunes of the former of these afford a guarantee on which the public may depend, in dealing with any respectable society of this sort; whilst, by receiving a share of the profits, the assured gain by the flourishing condition of the association, and it is of less consequence to them though the premium should be too high.

The *whole* profits of Mutual Assurance societies being divided amongst the assured, render such establishments of very great value, particularly to young lives; instances having frequently occurred of more than double the amount assured on one life being paid at the termination of a long standing policy in one of these societies. It has been objected to them, that every one being a partner of the concern, has not only his own life assured, but is part assurer of the lives of all the other members, and may, in this capacity, incur some serious responsibilities; but in this there is a material mistake, since it is a stipulation in the contract of copartnery of every such society, that the funds of the society alone shall be liable for their losses; and thus, though there may be a distant possibility of the sums assured not being paid in full, it is directly undertaken by every individual entering the society, that no claim shall be made on his account upon any of the other members. Moreover, when it is considered that the premiums required by all the assurance companies are very much higher than the risk demands, and that those of Mutual Assurance societies are among the highest, there is little danger, when due precaution is taken in accepting lives, of any loss being incurred by partaking of the benefits of this description of society. This will be placed in a still clearer view by the perusal of the following table from Mr Babbage's work on life assurance, exhibiting the profit per cent. on the premiums of several English offices, on an assurance on a life aged forty-six, which is about one year less than the average age of persons assuring.

Alliance	30·2

The most important points to be attended to in this description of insurance are the following.

1. No life assurance can be effected without an interest in the life. This was enacted to prevent gambling transactions, by stat. 14 Geo. III. c. 48, sect. 1, which declares that " no insurance shall be made by any person or persons, bodies politic or corporate, on the life or lives of any person or persons, or any other event or events whatsoever, where the person or persons for whose use or benefit, or on whose account, such policy or policies shall be made, *shall have no interest*, or by way of gaining or wagering; and that every insurance made contrary to the true intent and meaning of this act shall be null and void to all intents and purposes whatsoever." Under this act it has been found, that though a *bona fide* creditor has a sufficient interest in the life of his debtor to enable him to effect a valid assurance on such life; still, that in the case of money won at play, the creditor has not an assurable interest in the life of the individual who lost the money to him.

2. Life assurances are always assignable; indeed were they otherwise, assurance on lives would lose much of its utility. It is an every-day occurrence for a debtor to open a policy on his own life, and to assign it in security; and there can be no ground for pleading the extinction of the policy on his payment of the debt; for the benefit of the assurance still belongs to him, and he may make it the means of credit on another occasion, or dispose of it by settlement or otherwise. Assignment in sequestration carries a policy of life assurance; and if the debtor has secretly disposed of it after his bankruptcy, the person to whom it has been assigned will be bound to return any money drawn under it as for the use of the creditors. In the case of Schondler *v.* Wace, the bankrupt held a policy upon his own life, which, after bankruptcy, he sold to Wace for a lottery ticket. He died, and Wace received the sum assured. The assignees under the commission brought an action for recovery, and it was found that this

was a possibility of benefit to which they were entitled, as part of the bankrupt's effects; the defendant having a right, however, to deduct his outlay.

3. As the conditions in fire insurance form part of the contract; so, in life assurance, the declaration made previously to the policy being extended, is considered as part and parcel thereof. In this declaration it is stated that he whose life is to be assured "has no disorder tending to the shortening of life;" but this does not imply that he is free from all complaints, provided he be in a reasonably good state of health. Nor does it appear to be sufficient evidence of the tendency of the disorder to shorten life, that the person had it at a former period, and afterwards died of it, if free from disease at the time of assuring.

4. The death must happen within a limited time, otherwise the assurers are not liable; and there is no doubt, if an individual whose life is assured for one year be fatally wounded during the existence of that policy, but linger till after the term limited in the contract, that his executors have no claim. When, however, an assurance of this description exists on a man's life who goes to sea, and the vessel in which he sailed is never afterwards heard of, a question arises for a jury to decide from the circumstances produced in evidence.

5. In almost every life policy there are several exceptions in limitation of the risk. These generally are, death abroad or at sea; entering into naval or military service without the previous consent of the company; death by suicide; death by the hand of justice; and, in some offices, also death by duelling. The three last, however, do not apply where the assurance is effected on the life of another.

6. The premium on life assurance is not returnable. If a person whose life was assured should commit suicide or be put to death by the hand of the executioner the next day after the risk commenced, there would be no return of premium.

7. Life assurances, when a loss happens upon them, must be paid according to the tenor of the agreement, in the full sum assured, as this sort of policy, from its nature, being on the life or death of man, does not admit of the distinction between total and partial losses.

III.—MARINE INSURANCE.

Most persons are in some degree acquainted with fire and life insurances; the security which they afford to individuals and families is a comfort which no one is willing to dispense withal. Hence the great increase in modern times of companies professing to afford this security; and hence the knowledge on the part of the public generally, of the nature and principles of the engagements into which these companies enter. But marine insurance is a subject of immediate interest only to merchants and ship-owners; and in times of peace it is, even to them, of a much less engrossing nature than during the bustle and excitement of a Continental or an American war.

It is used as a means of indemnification for loss or damage to ships or goods whilst at sea, and that arising either from the elements or the enemy. From its nature there is no doubt of its being of a much more ancient date than either of the preceding, its introduction having generally been attributed to the Lombards and Venetians, the great carrying traders of Europe during the thirteenth, fourteenth, and fifteenth centuries. On the Continent it has consequently been longer practised, and is there much better understood than either fire or life insurance. The famous *Ordonnance de la Marine* of Louis XIV. was published in 1681, and has ever since been a standard work on this subject. In England there are few positive enactments to regulate marine insurance, its practice having been conformed to general principles and the usage of trade. The endless variety of circumstances connected with it naturally render it a much more abstruse and difficult subject than any other kind of insurance; and the numerous points, as sea-worthiness, deviation, capture, and others, which must be attended to, have from time to time created a vast variety of most complex and difficult cases in our law courts. Upon these the laws of British marine insurance are founded.

The nature of this contract is similar to those of the other descriptions of insurance. Suppose it has been remarked, that of fifty ships of the ordinary degree of sea-worthiness, employed in a given trade, one is on an average annually cast away; the probability of loss will plainly be equal to one fiftieth: and if an individual wish to insure a ship, or the cargo on board a ship, engaged in this trade, he ought to pay a premium equal to the one fiftieth part of the sum he insures, exclusively of such an additional sum as may be required to indemnify the insurer for his trouble, and to leave him a fair profit. If the premium exceed this sum, the insurer is overpaid; if it fall below it, he is underpaid. In this country marine insurance has always been for the most part effected with individuals; and of these the subscribers to Lloyd's have, from the extent of their transactions, been long the most distinguished. When a merchant or ship-owner desires to effect an insurance, he fills up a blank policy, so as to meet the particular object in view; he then hands it to one of the members of the room, who either rejects it, or underwrites for a certain limited sum; from him it goes to another; and thus it is handed about until the amount required is complete. Agents are appointed in all the principal parts of the world, who forward regularly to Lloyd's, accounts of all the arrivals at, and departures from, their ports, as well as of losses and other casualties, and, in general, all such information as may be supposed of importance towards guiding the judgments of the underwriters. In addition to this, there are annually published certain register books for shipping, which give an account of the tonnage, build, age, repairs, and quality of almost all the vessels that frequent our ports; and which, though in many respects defective, are material assistants to the insurers. Besides the subscribers to Lloyd's, there are many wealthy individuals, both in London and in all the considerable sea-ports of the kingdom, who underwrite policies of marine insurance. As these cannot be personally known to many of the ship-owners, a set of middle-men, or brokers, have arisen, whose business it is to receive orders for insurance, who apply to the persons they suppose most likely to cover the risks; and also become responsible for them being effected with accuracy and celerity.

Many of the inconveniences attending this mode of effecting insurance, particularly in the saving of time, are obviated when the business is transacted with a company. In such a case, the party having property to insure goes directly to the manager of the company, and states the particulars of the risk to be insured; when the premium is agreed on, the manager writes out a memorandum of the policy, which the party signs, and he is thus effectually insured before he leaves the office. The security afforded by such companies is also of infinite importance to the insured; severe and heavy losses having frequently occurred, from the bankruptcy or inability of individual underwriters. The Royal Exchange, Alliance Marine, Indemnity Mutual Marine, and London Assurance, are the principal companies for marine insurance in the metropolis; and, as well as the private underwriters mentioned above, there are similar establishments, though on a smaller scale, in most of the large sea-ports of the empire.

With respect to the rates of premium charged for marine insurance, it is self-evident that these will vary ac-

Marine Insurance.

cording to the seasons, the quality of the vessel, the known character of the captain, the nature of the commodity, and the state of our political relations. Of these no comprehensive table could be constructed, and therefore they come naturally to be regulated very much by general experience and particular information. All policies of marine insurance must be on stamped paper, the duties on which are as follows, viz.

On coasting voyages,	when the premium does not exceed twenty shillings per cent.	L.0 1 3
Ditto,	when the premium is above twenty shillings per cent.	0 2 6
On foreign voyages,	when the premium does not exceed fifteen shillings per cent.	0 1 3
Ditto,	when the premium does not exceed thirty shillings per cent.	0 2 6
Ditto,	when the premium is above thirty shillings per cent.	0 5 0

When reckoned by time, two shillings and sixpence per cent. is charged when under three months, and five shillings when the voyage exceeds that period.

It would be quite foreign to the purpose of the present work were we to enter upon the legal details of marine insurance. On this point the standard English authors, Park and Marshall, and the work of the learned professor of Scotch Law, Mr Bell, afford every possible information. We shall merely take notice of the following circumstances to be attended to in the contract.

1. The name of the insured or his agent is required by statute. By 28 Geo. III. c. 65, it is enacted, that it shall not be lawful for any person or persons to make or effect, or cause to be made or effected, any policy of insurance upon any ship, without first inserting, or causing to be inserted, in such policy or policies of insurance, the name or names, or the usual style and firm of dealing, of one or more of the persons interested in each insurance. This was required to remedy the evil of policies being issued in which the name of the insured was purposely left blank.

2. The names of the ship and master are necessary to identify the subject-matter of the policy; for whether it be ship, or freight, or goods, the risk attaches itself to a particular bottom. The place and time at which the risk is to commence and terminate are obviously requisite particulars; but the subject of the insurance is the essential part or *sine qua non* of the contract, for there must be no room to question what property is really put in risk.

3. The policy must be subscribed or underwritten with the names of the several insurers, each adding to his name the sum for which he is liable; and this may be done by a procurator acting under either express or tacit delegation. No witnesses are required.

4. The insured are under certain obligations in respect to representation and warranty of the facts whereon the undertaking of indemnity is grounded. Insurance being a contract of faith, in which the insurer is to rely for the most part on the statement of the insured, his representation of the facts must be fair and open; there must be no misrepresentation, no false insinuation, no concealment of circumstances material to the risk. Warranty, again, is an absolute condition expressed or implied, relative to the state or circumstances of the subject insured, which, if not true, or not complied with, defeats the insurance, whether material to the risk or not. A warranty may be affirmative, as that a ship was safe on a particular day; or promissory, that the ship will proceed with the convoy, or sail on a day certain; express, as that the ship is to sail on a day certain, or that she was on a certain day safe in harbour; or implied, including all those conditions relative to the risk which necessarily enter into the conception of the contract, as that the ship is seaworthy, that the voyage is lawful, that there shall be no deviation, and so on.

5. Policies are of two kinds, valued and open. By the former, the value of the subject insured is fixed by agreement of the parties, so that when a loss occurs, the value stated in the policy regulates the settlement, without regard to the original cost or invoice of the subject insured. By the latter the value is left open, and in case of loss the assured must adduce evidence of his interest, and he recovers indemnification only to the actual extent of his loss. In the settlement of a loss under an open policy, the ship is valued at what she was worth at the time of sailing, including her stores; the freight, at the amount which she would have earned according to the charter-party; and the cargo, at the invoice price, including the premium of insurance, and all charges.

6. Losses may be said to be of three kinds; total, general average, and partial loss. The former consists not solely in the entire destruction of the subject insured, but in such damage as to render it of little or no value to the owner, or at least to frustrate the adventure the securing of which was the object of the insurance.

When the total loss is manifest and undoubted, as where a ship is lost and is never heard of again, it falls directly upon the underwriter; but where any thing remains, the claim for loss must be accompanied by abandonment, which is a renunciation to the underwriter of all right, title, and claim to what may be saved, leaving it to him to make the most of it for his own benefit. In abandoning, the insured must make up his mind *tempestive;* but he is not bound to do so till he has an opportunity of receiving correct information. The common custom now-a-days, in paying such losses, is for the underwriter to settle for a certain per-centage, retaining a sum equivalent to the probable proceeds, leaving the insured to recover the savings, and settling the balance of the loss when these are ascertained.

General average is constituted by the voluntary sacrifice of the ship's materials, or part of the cargo, or when charges are incurred for the general benefit, such as the cutting from anchors and cables to avoid a lee shore, jetson of part of the cargo to lighten the vessel, expenses of taking the ship off the strand, &c.; in which, and all similar cases, the loss and expenses are borne by ship, cargo, and freight, in proportion to their respective values saved.

Partial loss, or, as it is in general termed, *particular average*, means a loss or damage by unavoidable accidents, not amounting to a total loss. Under it is included damage to the ship by stranding, by unavoidable collision with another vessel, damage to the hull, boats, masts, or other parts, by a stroke of the sea, by lightning, accidental fire, &c. These, and such like, are of the nature of particular average on the ship; but the springing of a leak at sea, or the splitting of sails, or the parting of a cable, and similar damages, are held to be the ordinary wear and tear of the ship, and which the owner cannot recover from the underwriter.

Particular average on the cargo means damage by sea-water, fire, or any accident which the care of the master and crew could not prevent. (See article AVERAGE.)

7. The mode of settlement after the damage is ascertained is likewise an important subject.

In adjusting a partial loss on a ship, it is usual to deduct one third from the new materials and labour, except on certain articles, unless the ship or the materials injured were perfectly new. When the loss is on cargo, it is settled either by taking the invoice price and deducting the nett proceeds of sale of the damaged goods, or by comparing the amount of sales of the damaged goods with a *pro forma* account of sales of the same articles if they had arrived in a sound state. The former of these, termed a *salvage* loss, is the mode of adjustment where the goods required to be sold short of the port of destination, and where it was consequently impossible to refer to the market price of that port, as in the second instance. The latter method avoids involving the underwriters in a falling or rising market; the market price of the sound and of the damaged commodities being said to be the scales in which to weigh the depreciation.

INTAGLIOS, precious stones, on which are engraved the heads of great men, inscriptions, and the like; such as we frequently see set on rings, seals, and other ornamental articles.

INTEGER, in *Arithmetic*, a whole number, in contradistinction to a fraction.

INTEGRAL, or INTEGRANT, in *Philosophy*, appellations given to parts of bodies which are of a similar nature with the whole. Thus filings of iron have the same nature and properties as bars of iron.

Bodies may be reduced into their integrant parts by triture or grinding, limation or filing, solution, amalgamation, and other processes.

INTEGRAL *Calculus*, in the new analysis, is the reverse of the differential calculus, and is the finding of the integral from a given differential, being similar to the inverse method of fluxions. See FLUXIONS.

INTELLECT, a term used amongst philosophers to signify that faculty of the soul usually called the *understanding*. See LOGIC and METAPHYSICS.

INTENDANT, one who has the conduct, inspection, and management of any thing.

INTENDMENT, in *Law*, is the intention, design, or true meaning, of a person or thing, which frequently supplies what is not fully expressed; but though the intention of parties in deeds and contracts is much regarded by the law, yet it cannot take place against the rules of law.

INTENDMENT *of Crimes*. This, in case of treason, where the intention is proved by circumstances, is punishable in the same manner as if it had actually been put in execution.

INTENT, in the civil law, signifies to begin or commence an action or process.

INTENTION, in *Physics*, the increase of the power or energy of any quality, as heat or cold, by which it stands opposed to *remission*, which signifies its decrease or diminution.

INTENTION, in *Metaphysics*, denotes an exertion of the intellectual faculties with more than ordinary vigour, when the mind earnestly fixes its view on any idea, considers it on all sides, and cannot be called off by any solicitation.

INTERCALARY, an appellation given to the odd day inserted in leap-year; which was so called from *calo, calare*, to proclaim, it being proclaimed with a loud voice by the priests.

INTERCESSION (*intercessio*) was used in ancient Rome for the act of a tribune of the people, or other magistrate, by which he inhibited the acts of other magistrates; and even, in the case of the tribunes, the decrees of the senate. *Veto* was the solemn word used by the tribunes when they inhibited any decree of the senate, or law proposed to the people. The general principle of these intercessions was, that any magistrate might inhibit the acts of his equal or inferior; but the tribunes had the sole prerogative of controlling the acts of every other magistrate, yet could not themselves be controlled by any.

INTERCESSOR (from *inter* and *cedo*, I go between), a person who prays, expostulates, or intercedes, in behalf of another. In the Roman law, intercessor was the name of an officer, whom the governors of provinces appointed principally to raise taxes and other duties.

INTERCESSOR is also a term which was heretofore applied to such bishops as, during the vacancy of a see, administered the bishopric till a successor to the deceased prelate had been elected. The third council of Carthage calls these *interventors*.

INTERCOLUMNIATION, in *Architecture*, denotes the space between two columns, which is always proportioned to the height and bulk of the columns.

INTERCOSTAL, in *Anatomy*, an appellation given to such muscles, nerves, arteries, and veins, as lie between the ribs.

INTERDICT, an ecclesiastical censure, by which the church of Rome forbids the performance of divine service in a kingdom, province, or town. This censure has frequently been enforced in France, Italy, and Germany; and, in the year 1170, Pope Alexander III. put all England under an interdict, forbidding the clergy to perform any part of divine service, except baptizing infants, taking confessions, and giving absolution to dying penitents. But this censure being liable to the evil consequences of promoting libertinism and a neglect of religion, the succeeding popes have very seldom had recourse to it.

There was also an interdict of persons, who were deprived of the benefit of attending at divine service. Particular persons were also anciently interdicted the use of fire and water, which signified a banishment for some particular offence. By this census no person was permitted to receive them, or allow them the use of fire or water; and being thus wholly deprived of the two necessary elements of life, they were doubtless under a sentence of proscription.

INTEREST

Is the sum which the borrower of a *capital* obliges himself to pay to the lender for its *use*.[1]

Formerly it was universally believed that, in the event of all legislative enactments fixing and regulating the rate of interest being repealed, its increase or diminution would depend wholly on the comparative scarcity or abundance of money; or, in other words, that it would rise as money became scarce, and fall as it became more plentiful. Mr Hume was the first to point out the fallacy of this opinion,[2] and to show that the rate of interest is not determined by the amount of the currency, but by *the average rate of profit derived from the employment of capital*. No doubt it most frequently happens that, when a loan is made, it is made in the currency of the country. This, however,

[1] Interêt: loyer d'un *capital* preté; ou bien, en termes plus exacts, achat des *services productifs* que peut rendre un capital. (Say, tome ii. p. 480, ed. 4me.

[2] See his *Essay on Interest*.

is really of no consequence. There is obviously no difference between one individual furnishing another with 100 bushels of corn, to be repaid at the expiration of a twelvemonth by the delivery of 104 or 105 bushels, or with as much money at four or five per cent. as would have purchased the corn. Besides, it is easy to perceive that the same identical sum of money might serve to negotiate an infinity of loans. Suppose A lends to X L.1000, which X immediately pays away to B for commoditics of equal value; but B has no use for the money, and he therefore lends it to Y, who pays it away for commodities to C, who again lends it to Z, and so on; it is plain the borrowers X, Y, Z, have really received a loan of commodities, or capital, from the lenders A, B, C, worth *three* times (and it might have been worth three hundred or three thousand times) as much as the money employed in settling the transactions. According as the supply of currency, compared with the business it has to perform, is greater or less, we are obliged to give a greater or less number of guineas or livres, pound notes or assignats, for the commodities we wish to obtain. It is plainly, however, by the *advantage* or *profit* we expect to derive from the acquisition of the commodities which constitute capital, and not from the accidental, and, in this respect, unimportant, circumstance of a larger or smaller number of pieces of gold or silver, or of bits of engraved paper, being given for them, that the rate of interest, or the compensation given to the lender for the use of his stock, must be determined. It may perhaps be supposed, that when the quantity of metallic money is increased, goldsmiths, jewellers, &c. obtain the raw material for carrying on their business with greater facility; but this is not always the case, and, though it were, it would not affect the rate of interest. No coins are ever sent to the melting pot unless when the currency is either degraded or depreciated; that is, unless it be deficient in weight, or *relatively* redundant in quantity. And it is clear that the inducement to promise a high or low rate of interest for loans of metallic money, which it was intended to work up into some species of manufactured goods, would depend, not on the supply of such money, but on the profit to be derived from the operation, a circumstance totally unconnected with the scarcity or abundance of coin.

It appears, therefore, that the rate of interest, at any given period, depends exclusively on the supply of real disposable capital, such as land, machinery, raw and manufactured products, &c. compared with the power of profitably employing it. An increase of metallic money adds only very inconsiderably, and an increase of paper money adds nothing whatever, to the real capital of the country, or to the material of which all loans are really composed. If an increase of paper money was equivalent to an increase of capital, bank notes could not be too much multiplied, and France would have been about twenty times as rich at the era of the assignats as at this moment. It is not denied that considerable mischief and derangement must always be experienced in a highly manufacturing and commercial country like Great Britain, when any sudden check is given to the facility with which discounts are generally obtained, or when the currency is suddenly contracted. But the *frottement* and inconvenience occasioned by a contraction of the currency could only be temporary. It is impossible it could have any lasting effect on the industry of the country. We should still possess the same amount of real capital; and as neither its productive power, nor the liberty to transfer it from one individual to another, would be at all impaired, the real revenue of the state would continue as great as ever, and the same or a greater amount of stock might be disposed of by way of loan. *Money prices* would certainly fall proportionally to the reduction of the currency; or, which is the same thing, the value of commodities would henceforth have to be ascertained by comparing them with a smaller number of bits of gold or paper. But, in every other respect, the business of society would continue exactly on its former footing; and, without some change in the rate of profit, on which fluctuations in the value of money have almost no effect, the rate of interest would continue invariable.

Mr Ricardo has set this principle in a clear and striking point of view. "The rate of interest," he observes, in answer to those who had contended that it would be increased by a diminution of the discounts of the Bank of England, "is not regulated by the rate at which the bank will lend, whether it be five, four, or three per cent., but by the rate of profit which can be made by the employment of capital, and which is totally independent of the quantity and of the value of money. Whether a bank lend one million, ten millions, or a hundred millions, they would not permanently alter the market rate of interest; they would alter only the value of the money which they thus issued. In one case ten or twenty times more money might be required to carry on the same business, than what might be required on the other. The applications to the bank for money, then, depend on the comparison between the rate of profits that may be made by the employment of it, and the rate at which they are willing to lend it. If they charge less than the market rate of interest, there is no amount of money which they might not lend; if they charge more than that rate, none but spendthrifts and prodigals would be found to borrow of them. We accordingly find, that when the market rate of interest exceeds the rate of five per cent. at which the bank uniformly lend, the discount office is besieged with applicants for money; and, on the contrary, when the market rate is even temporarily under five per cent., the clerks of that office have no employment."[1]

It is foreign to the object of this article to enter into any detailed examination of the causes which tend to elevate or depress the rate of profit. Whatever diversity of opinion may be entertained respecting them, it is abundantly evident that the rate of interest afforded for the use of borrowed capital must be proportional to the profits which might be derived from its employment. In the United States, the market rate of interest varies from ten to fourteen per cent.; and in Holland, previously to the invasion of the French in 1794, it did not exceed two or three per cent. The immense extent of fertile and uncultivated land in America, the lowness of taxation, and the absence of all restrictive regulations, naturally occasion high profits, and consequently high interest; whilst the sterility and limited extent of the soil of Holland, the excessive load of taxes, laid equally on necessaries and luxuries, and the injudicious restraints imposed upon various branches of commerce, by rendering it impossible to derive large returns from capital, proportionally sink the rate of interest. Had the soil of Holland been as fertile, and taxation as light, as in the United States, profits and interest would, notwithstanding the abundant supply of capital, have been equally high in the one republic as in the other. It is not by the absolute amount of the stock of a country, but by the comparative facilities for its advantageous employment, that the compensation or interest which a borrower can afford for its use must always be regulated. Previously to the termination of the late war, the market rate of interest in this country, for sums which could not be immediately demanded, fluctuated from five to twelve

[1] Ricardo's *Principles of Political Economy*, 1st edit. p. 511.

Interest.

per cent. It has since fallen to four or five per cent.; a decline which has not certainly been occasioned by any sudden increase of capital, but by the extraordinary depression of commerce, and the consequent impossibility of investing stock so as to yield as large a profit as it did during the period when we engrossed almost the whole trade of the world.

Rate of interest varies according to the security for the payment of the principal and duration of the loan.

Besides such variations as are proportional to variations in the general and average rate of profit, and which *equally* affect *all* loans, the rate of interest must vary according *to the degree of security afforded for the repayment of the principal, and the duration of the loan.* No capitalist would lend on the personal security of a gunpowder manufacturer, and on *mortgage* over a valuable estate, at the same rate of interest. The extraordinary hazard of the gunpowder trade exposes the stock invested in it to an extreme degree of *risk.* It may be dissipated in an instant, and the power of the borrower to refund the capital he had borrowed annihilated for ever. A lender of money on mortgage is almost entirely relieved from such contingencies. The owner of an estate on which a loan is secured may become bankrupt; but the estate itself will remain, and may either be sold or taken possession of by the lender. It is plain, therefore, that there must be a very great difference in the rate of interest paid by those whose security for the repayment of the principal is so exceedingly different. The gunpowder manufacturer, besides paying a rate or per-centage equivalent to the common and average rate of interest derived from the most secure investments, would have to pay an *additional* rate, which, although it might not be designated by that name, would really constitute a *premium* of insurance proportioned to the greater risk to which the lender was exposed of losing his principal. The preferable security offered by the landholder would relieve him from the necessity of paying any considerable premium, or excess of interest, on account of risk; and of course he would be able to borrow at so much less than the manufacturer. We should mistake, however, if we supposed that the latter was thus placed in a comparatively disadvantageous situation. He would be completely indemnified for the greater risk to which his stock was exposed, and for the higher rate of interest which he was in consequence obliged to pay, by the greater *gross profits* he would derive from his business. The constantly operating principle of competition will not permit, taking every thing into account, a greater *nett profit* to be permanently derived from one department of industry than from another. But those who invest their stock in employments of more than ordinary hazard, must be able to dispose of their produce at such a price as will yield them the common and average rate of profit, besides affording a surplus adequate to insure their stock against the extra risk to which it is exposed. If this were not the case, no capitalist would place his property in a state of comparative danger, and no undertakings of a hazardous nature would be entered into. Wherever there is risk, that risk must be compensated. And it may, and very frequently does, happen, that the manager of a hazardous branch of industry, paying from ten to twenty per cent. for borrowed capital, is realizing a larger nett profit than the landlord who has purchased an estate with money for which he only pays three or four per cent.[1]

But supposing the securities to be equal, capital lent for *short* periods, or in such a way that the lender may obtain possession of it *at pleasure,* will always bring a lower rate of interest than capital lent for a considerable or definite period. No borrower could afford to pay so high a rate of interest for a capital whose productive services he might be deprived of in an instant, and which he could not therefore venture to invest in any employment from which it might not be easily withdrawn, as for a capital lent for a fixed period, especially if that period was of considerable length. But here, as in every other case, the real interests of the borrower and lender coincide. The same circumstances which prevent a borrower from giving as high a rate of interest for a loan payable on demand as if it were payable at a fixed and distant term, induces the lender to rest satisfied with a smaller compensation in the one case than in the other. We wish to be able to exercise a complete command over our capital. No merchant would ever consent to lend his stock on mortgage. If he did, he would no longer be able to carry on his business with advantage. He would be deprived of all power of speculating; and although this might in many instances be for his advantage, yet the flattering opinion which every one entertains of his own abilities and good fortune would but seldom allow him to doubt of its being a very material disadvantage. It is by this principle that we are able to account for the comparatively low rate of interest at which banking companies who pay the sums deposited with them on demand, and governments whose circumstances are perfectly desperate, are able to borrow. A stockholder's mortgage (his claim on the revenue of the country) can be immediately converted into cash at the current prices. And, however much the majority of the public creditors may be impressed with a conviction of the inability of the state to discharge *all* the claims upon it, every particular individual, confident in his own good fortune, foresight, and acuteness, flatters himself with the idea that *he,* at least, will be able to predict the coming tempest, and that *he* will be able to sell out before a national bankruptcy.

Interference of government in adjusting the rate of interest.

Instead, however, of leaving the rate of interest to be adjusted by the unfettered competition of the borrowers and lenders, on the principles we have thus briefly explained, the governments of most countries have interfered, either to prohibit the taking interest altogether, or to fix certain rates which it was declared legal to exact, at the same time that any excess over these rates was declared to be *usury,* and prohibited under the severest penalties. In the rude and unenlightened ages in which these enactments had their origin, the precious metals, then the only species of money, were considered as uninfluenced by the same principles which regulate the value of other products. Being used both as standards whereby to ascertain the comparative value of different commodities, and as the equivalents for which they were most frequently exchanged, they acquired a factitious importance, not merely in the estimation of the vulgar, but in that of persons of the greatest discernment. The simple consideration that all buying and selling is really nothing more than the bartering of one commodity for another, of a certain quantity of corn or beef, for example, for a certain quantity of gold or silver, and *vice versa,* was entirely overlooked. The attention was gradually trans-

[1] This principle is never lost sight of in bargaining for loans. In Athens, the rate of interest was not regulated by law; and it is distinctly mentioned by ancient authors, that the average rate of interest paid by those who employed their stock in the shipping trade with the countries situated on the Euxine and Mediterranean Seas amounted, on account of the hazard of the voyage, to about thirty per cent.; whilst bankers, agriculturists, and others, whose security was preferable, paid only about twelve per cent. Say, in noticing this striking fact, supposes that the thirty per cent. was charged by the voyage; and that, as two voyages to the Crimea or Sicily might be made annually, *maritime* interest really amounted at Athens to sixty per cent. There does not, however, appear to be the least ground for this assertion. It is the average annual rate of interest that is always spoken of. (*Travels of Anacharsis*, vol. iv. p. 368, Eng. Transl.; De Pauw, *Récherches sur les Grecs*, tom. i. p. 287; Say, tom. ii. p. 132.)

Interest.

ferred from the money's worth to the money itself; and the wealth of states and of individuals came to be measured, not by the abundance of their disposable produce, by the quantity or value of the commodities with which they could afford to purchase the precious metals, but by the *quantity of these metals* actually in their possession. Because it sometimes happened that the holders of ordinary commodities were unable easily to dispose of them at any price, whilst money was always sure to find a ready and advantageous market, it was considered as something mysterious, as a real *marchandise par excellence.* We cannot, therefore, be surprised at the measures to which the erroneous opinions entertained respecting it necessarily led; or that efforts should have been made to protect the interests of those who were unprovided with so powerful an instrument, from becoming a prey to the encroachments of their more fortunate neighbours. Every individual was allowed freely to dispose of his corn, cattle, land, &c.; but it was imagined there was something peculiar in money, and that the desire to obtain it was so great, that, unless the lenders were restrained in their demands, they would, by taking advantage of the necessities of the borrowers, infallibly ruin them, and engross the whole property of the country.

Another source of the prejudice against stipulating for interest must be sought for in the dislike so universally entertained in remote ages to accumulation. There can be no accumulation without economy, without a saving of income; and this was then not only considered as indicative of a sordid and avaricious disposition, but as being positively hurtful. Before the nature and functions of capital were properly understood, it was believed that it could not be increased otherwise than by injuriously abstracting a portion of the national revenue, and that any advantage it might give to the proprietor must have been obtained at the public expense. It did not occur to our ancestors, that an individual who, by his economy, has accumulated stock, has really added to the wealth of the state, without diminishing that of others; nor were they aware that this stock, when afterwards expended, as is almost always the case, in the support of productive industry, would afford the means of producing an increased income. But reckoning, as they did, the savings of individuals as so much withdrawn from the public income, it was natural enough that they should endeavour to limit the advantage to be derived from their employment.

Much, also, of the prejudice against bargaining for interest, so prevalent in the middle ages, may be traced to the authority of some texts of Scripture, which were understood entirely to prohibit its exaction. It has, however, been shown, that these texts will not really bear this interpretation; but, supposing that they did, nothing, it is plain, could be more absurd than to consider the municipal regulations of a people placed in such peculiar circumstances as the Jews, as general and fixed principles, applicable in all ages and countries.

The attempts to limit the rate of interest, instead of reducing, have contributed to raise it.

But, whatever may have been the causes of the efforts so generally made to regulate and limit the rate of interest, it is certain that, so far from succeeding in their object, they have had a precisely opposite effect. Should a borrower find it for his advantage to offer six, seven, or eight per cent. for a loan (and unless it were for his advantage, nothing could possibly induce him to make such an offer), what right has the legislator to interfere, and to prohibit the lender from receiving, and the borrower from paying, more than four or five per cent.? Such an interference is not only uncalled for and unnecessary, but it is, in the highest degree, prejudicial. Restrictive laws, instead of reducing, have uniformly contributed to raise the rate of interest. Nor is this any thing more than might have been foreseen and expected. It is plain that no law can be so framed as to prevent a borrower from offering a higher rate of interest than what is fixed by statute; and if the lender had implicit confidence in the secrecy and solvency of the borrower, he might accommodate him with the sum wanted, without requiring any additional interest or *premium of insurance* because of the danger of entering into what the law declares to be an *illegal* transaction. But this must be a very rare case. Gratitude, and a sense of benefits received, are, unfortunately, when they come into contact with self-interest, but slender securities for honourable conduct. Numberless unforeseen events occur to weaken and dissolve the best cemented friendships; and a transaction of this kind would undoubtedly afford an additional source of jealousies and divisions. In such matters, indeed, men are more than usually sharp-sighted, and are very little disposed to trust to moral guarantees for the security of their property. But neither the threatenings of the law, nor the powerful inducements which it holds out to dishonest debtors to break their engagements, and treacherously to recede from the stipulations to which they had agreed, have been able to prevent, or even greatly to lessen, what are termed *usurious* bargains. Their only effect has been, to oblige the lender to demand, and the borrower to bind himself to pay, a higher rate of interest than would otherwise have been required. A bargain for more than the statute rate of interest being declared illegal, the lender is thus exposed to an additional *risk.* But no person will gratuitously place his fortune in a situation of comparative hazard; and, therefore, the sum necessary to cover this risk must be proportioned to the greater or less anxiety on the part of government to prevent and punish such bargains; or, in other words, the rate of interest is invariably increased according as the laws intended to reduce it become more severe, and diminished according as they are relaxed.

Thus a capitalist might be inclined to lend a sum at six or seven per cent.; but as the law declares that any individual who shall stipulate for more than five per cent. shall, if detected, forfeit *three times the principal*, it is clear, provided there was no method of defeating this statute, that there must be an end of all borrowing, except when the market rate of interest was below the statutory rate. Whenever it was above that rate, no person would be able to obtain a single farthing in the way of loan. There could, then, be no transference of capital. It would continue locked up in the same hands; and the national property and welfare would, in consequence, suffer severely. Luckily, however, the mutual interest and ingenuity of borrowers and lenders have always proved an overmatch for the enactments of the law. These have done nothing but fetter the transference of stock, and force the borrowers to pay a higher rate of interest for it. What might have been borrowed at six per cent., had there been no hazard from anti-usurious statutes, is, on account of that hazard, raised to perhaps eight or even ten per cent.; and, what is still worse, a contempt for the institutions of society, and a habit of carrying on business in a secret and underhand manner, are generated. The odium which attaches to a positively pernicious regulation, weakens the respect which would otherwise be felt for those which are acknowledged to be advantageous; and that spirit of frankness, openness, and sincerity, which, wherever it predominates, is so highly valuable, is cramped in its development, or altogether supplanted, by duplicity, extortion, and cunning.

Effect of the usury laws at Rome.

These conclusions do not rest on theory only, but are supported by a constant and uniform experience. At Rome, during the period of the republic, the ordinary rate of interest was excessively high. The debtors, or plebeians, were every now and then threatening to deprive their creditors, who were generally of the patrician

Interest.

order, not only of the interest of their capital, but of the principal itself. Repeated instances occurred to show that these were not mere empty threats; and the patricians were therefore obliged to indemnify themselves, by means of a corresponding premium, for the risks to which they were exposed. "Des continuels changements," says Montesquieu, "soit par des loix, soit par des plebiscites, naturaliserent à Rome l'usure; car les créanciers, voyant le peuple leur débiteur, leur legislateur, et leur juge, n'eurent plus de confiance dans les contrats. Le peuple, comme un débiteur decrédité, ne tentoit à lui prêter que par *des gros profits;* d'autant plus que, si les loix ne venoient que de temps en temps, les plaintes du peuple étoient continuelles, et intimidoient toujours les créanciers. Cela fit que tous les moyens honnêtes de prêter et d'emprunter furent abolis à Rome, *et qu'une usure affreuse, toujours foudroyée, et toujours renaissante, s'y établit.* Le mal venoient de ce que les choses n'avoient pas été ménagés. Les loix extrêmes dans le bien font naître le mal extréme: *il fallut payer pour le prêt de l'argent, et pour le danger des peines de la loi.*" (*Esprit des Loix*, livre xxii. chap. 21.)

In the East.

In Mahommedan countries, notwithstanding the positive prohibition in the Koran, the ordinary rate of interest is at least ten or twenty times as high as its ordinary rate in Europe. "L'usure augmente dans les pays Mahometans *à proportion de la sévérité de la defense:* le prêteur s'indemnise du péril de la contravention." (*Esprit des Loix*, liv. xxi. ch. 19.)

In the middle ages.

During the middle ages, the average rate of profit could not be much higher than at present: "But the clamour and persecution raised against those who took interest for the use of money was so violent, that they were obliged to charge it much higher than the natural price, which, if it had been let alone, would have found its level, in order to compensate for the opprobrium, and frequently the plunder, which they suffered; and hence the usual rate of interest was what we should now call most exorbitant and scandalous usury."[1] The extraordinary risks to which lenders were exposed rendered the premium of insurance on all sorts of capital excessively high; for, of the fifty and even a hundred per cent. which borrowers then frequently engaged to pay as interest, not more than eight or ten per cent. can properly be said to have been given for the productive services of capital. The rest must be considered as a *bonus*, to compensate the lender for the hazard he encountered of losing the principal itself.[2]

In France.

In France the rate of interest was fixed at five per cent. so early as 1665; and this, a few short intervals only excepted, continued to be the legal rate until the Revolution. Laverdy, in 1766, reduced it from five to four per cent. Instead, however, of the market rate being proportionably reduced, it was raised from five to six per cent. Previously to the promulgation of the edict, loans might have been obtained on good security at five per cent.; but an additional per cent. was now required to cover the risk of illegality. This caused the speedy abandonment of the measure.[3]

In Livonia.

The same thing happened in Livonia in 1786, when the Empress Catherine reduced the legal rate of interest from six to five per cent. Hitherto, says Storch (*in loco supra citato*), those who had good security to offer were able to borrow at six per cent.; but henceforth they had to pay seven per cent. or upwards. And such will be found to have been invariably the case, wherever governments have interfered to reduce the statutory below the market rate of interest.

History of the laws regulating the rate of interest in England.

From the earliest period of the history of England down to the reign of Henry VIII., the taking of interest was absolutely forbidden to all persons within the realm except Jews and foreigners, who, nevertheless, were frequently plundered for the sake of enriching the crown, under the miserable pretext of punishing them for what were then called their "hellish extortions." The disorders occasioned by this ruinous interference on the part of government at length became so obvious, that, notwithstanding the powerful prejudices to the contrary, a statute was passed in 1546 (37 Hen. VIII. cap. 7), legalizing the taking of interest to the extent of ten per cent. per annum; and this because, as is recited in the words of the act, the statutes "prohibiting interest altogether have so little force, that little or no punishment hath ensued to the offenders." In the reign of Edward VI. the horror against taking interest seems to have revived in full force; for, in 1552, the taking of *any* interest was again prohibited, "as a vice most odious and detestable," and "contrary to the word of God." But, in spite of this tremendous denunciation, the ordinary rate of interest, instead of being reduced, immediately rose to fourteen per cent., and continued at this rate until, in 1571, an act was passed (13 Eliz. cap. 8) repealing the act of Edward VI., and reviving the act of Henry VIII., allowing ten per cent. interest. In the preamble to this act it is stated, "that the prohibiting act of King Edward VI. had not done so much good as was hoped for; *but that rather the vice of usury hath much more exceedingly abounded*, to the utter undoing of many gentlemen, merchants, occupiers, and others, and to the importable hurt of the commonwealth." This salutary statute was opposed, even by those who, it might have been expected, would have been among the first to emancipate themselves from the prejudices of the age, with all the violence of ignorant superstition. Dr John Wilson, a man famous in his day, and celebrated for the extent and solidity of his learning, stated, in his place in the House of Commons, that "it was not the amount of the interest taken that constituted the crime; but that all lending for any gain, be it ever so little, was wickedness before God and man, and a damnable deed in itself, and that there was no mean in this vice any more than in murder or theft." In order to quiet the consciences of the bench of bishops, a clause was actually inserted, declaring *all* usury to have been forbidden by the law of God, and to be in its nature sin, and detestable. When first enacted, this statute was limited to a period of five years; but, "forasmuch as it was by proof and experience found to be very necessary and profitable for the commonwealth of this realm," it was, in the same reign, made perpetual. (39 Eliz. cap. 18.)

In the 21st of James I. the legal rate of interest was re-

---

[1] Macpherson's *History of Commerce*, vol. i. p. 400.

[2] It is impossible to form any very accurate estimate of the rate of profit in the middle ages; yet several striking facts may be adduced in support of the opinion advanced in the text. At Verona, in 1228, the interest of money was fixed by law at twelve and a half per cent. Towards the end of the fourteenth century, the republic of Genoa paid only from seven to ten per cent. to her creditors; and the average discount on good bills at Barcelona, in 1435, is stated to have been about ten per cent. But whilst the rate of interest in Italy and Catalonia, where a considerable degree of freedom was allowed to the parties concerned in bargaining for a loan, was thus comparatively moderate, it was, in despite of its total prohibition, incomparably higher in France and England. Matthew Paris mentions that, in the reign of Henry III., the debtor paid ten per cent. every two months; and this, though absolutely impossible as a general practice, may not have been very far from the average interest charged on the few loans that were then contracted for. (Hallam's *History of the Middle Ages*, vol. iii. p. 402.)

[3] Storch, *Traité d'Economie Politique*, tome iii. p. 187.

Interest.

duced to eight per cent., by an act to continue for seven years only, but which was made perpetual in the succeeding reign. (3 Car. I. cap. 4.) During the commonwealth, the legal rate of interest was reduced to six per cent., a reduction which was afterwards confirmed by the act 12 Car. II. And, finally, in the reign of Queen Anne, a statute (12 Anne, cap. 16) was framed, reducing the rate of interest to five per cent., at which it now stands.

In the preamble to this statute, it is stated, that, "whereas the reducing interest to ten, and from thence to eight, and thence to six, in the hundred, hath from time to time, by experience, been found very beneficial to the advancement of trade and the improvement of lands, it is become absolutely necessary to reduce the high rate of interest of six per cent. to a nearer proportion to the interest allowed for money in foreign states." It was for these reasons enacted, that all bargains or contracts stipulating for a higher rate of interest than five per cent. should be utterly void. And "that all persons who should after that time receive, by means of any corrupt bargain, loan, exchange, chevizance, or interest, of any wares, merchandise, or other thing whatever, or by any deceitful way or means, or by any covin, engine, or deceitful conveyance for the forbearing or giving day of payment, for one whole year, for their money or other thing, above the sum of L.5 for L.100 for a year, should forfeit, for every such offence, the *triple* value of the monies or other things so lent, bargained," &c.

Laws regulating the rate of interest in Scotland.

In Scotland, previously to the Reformation, no interest could be legally exacted for money. But this great event, by weakening the force of those religious prejudices, which had chiefly dictated the laws prohibiting interest, occasioned the adoption of sounder opinions on the subject, and led to the enactment of the statute of 1587 (11 Parlt. Jac. VI. cap. 52), which legalized the taking of interest to the extent of ten per cent. In 1633 the legal rate was reduced to eight per cent., and in 1661 to six per cent. The statute of Queen Anne, reducing the rate of interest to five per cent., extended to both kingdoms.

In Ireland.

The statutes prohibiting the taking of interest in Ireland were not repealed until 1635, when, by the statute 10 Car. I. cap. 22, liberty was given to stipulate for interest to the extent of ten per cent. In 1704 this rate was reduced to eight per cent.; in 1722 it was reduced to seven per cent.; and in 1732 it was further reduced to six per cent., at which it has since continued fixed.

Comparison between the market rate and the statutory rate of interest, from 1714 to 1793.

It has been observed by Dr Smith, that the different statutory regulations, reducing the rate of interest in England, were made with great propriety. Instead of preceding, they followed the fall which was gradually taking place in the market rate of interest; and, therefore, did not contribute, as they otherwise must have done, to raise the rate which they were intended to reduce. Sir Josiah Child, whose celebrated Treatise, recommending a reduction of interest to four per cent. was published about 1670, states positively, that the goldsmiths in London, who then acted as bankers, could obtain as much money as they pleased, upon their servants' notes only, at four and a half per cent. The supposed insecurity of the revolutionary establishment, and the novelty of the practice of funding, occasioned the payment of a high rate of interest for a considerable portion of the sums borrowed by the public in the reigns of William III. and Anne; but private persons, of undoubted credit, could then borrow at less than five per cent. During the reign of George II. the market rate of interest fluctuated from three to four and four and a half per cent.[1]

Dr Smith mentions, that the increased means of profitably investing capital acquired during the war which terminated in 1763, raised the market rate of interest, subsequently to the peace of Paris, to a level with the statutory rate, or perhaps higher. But this rise was only temporary, and it was not until the late war that any very material or general inconvenience was found to result from the limitation of the rate of interest to five per cent.

Expediency for defeating the laws limiting the rate of interest.

It is necessary, however, to observe, that this remark applies exclusively to the loans negotiated by individuals who could offer unexceptionable security; for, ever since the passing of the act 1714, persons engaged in employments of more than ordinary hazard, whose character for prudence and punctuality did not stand high, or who could only offer inferior security, were unable to borrow at five per cent., and have in consequence been compelled to resort to a variety of schemes for defeating and evading the enactments in the statute. The most common device was the sale of an annuity. Thus, supposing an individual whose personal credit was not good, and who had only the liferent of an estate to give in security, wanted to borrow any given sum, he sold an annuity to the lender sufficient to pay the interest stipulated for, which, because of the risks and odium attending such transactions, was always higher than the market rate, and also to pay the *premium* necessary to insure payment of the principal on the death of the borrower. It is curious to observe, that although the sale of an *irredeemable* life annuity, at a rate exceeding legal interest, was not reckoned fraudulent or usurious; yet, so late as 1743, Lord Hardwicke held, that in their less exceptionable form, or when they were *redeemable*, annuities could only be looked upon as an evasion of the statute of usury, and a loan of money.[2] But the extreme inexpediency of this distinction soon became obvious, and the law on this subject is now entirely changed. The greater extension of the traffic in annuities, and the advantage of giving as much publicity as possible to such transactions, led to various parliamentary inquiries and regulations respecting them in the early part of the reign of his late majesty. The consequence has been, that irredeemable annuities are now nearly unknown, and that the sale of a redeemable annuity cannot be impeached, although it should appear on the face of the deeds that the lender had secured the principal by effecting an assurance of the borrower's life.[3]

During the greater part of the late war, however, the usury laws operated, not to the prejudice of one, but of all classes of borrowers. The extent of the loans, the high rate of interest given by the state, the facility of selling out of the funds, the regularity with which the dividends were paid, and the temptations arising from the fluctuations in the price of funded property, diverted so large a proportion of the floating capital of the country into the coffers of the treasury, as to render it next to impossible for a private individual to borrow at the legal rate of interest, except from the trustees of public companies, or

---

[1] On the 18th of December 1752, the three per cents. brought the highest price they have hitherto reached, namely, 106⅝ per cent. On the 20th of September 1797, the day on which the failure of Lord Malmesbury's attempt to negotiate with the French republic transpired, consols fell to 47⅞, being the lowest price at which they have ever been sold.

[2] *Considerations on the Rate of Interest*, by E. B. Sugden, Esq. *Pamphleteer*, vol. viii. p. 278.

[3] By the act 53 Geo. III. cap. 141, it is enacted, "That a memorial, setting forth the date of every deed, bond, instrument, or other assurance, whereby an annuity or rent-charge shall be granted for one or more life or lives, or for a certain number of years, the names of all the witnesses, and of all the parties thereto, the sum given for the security, and the amount of the annuity itself, shall be registered in the Court of Chancery." This act only applies to England and Wales.

through the influence of circumstances of a very peculiar nature. The proprietors of unencumbered freehold estates, of which they had the absolute disposal, were almost universally obliged to resort to those destructive expedients which had formerly been the resource only of spendthrifts, and persons in the most desperate circumstances. Annuities were not unfrequently granted for the term of several lives, at the rate of twelve, fourteen, fifteen, and even twenty per cent., exclusive of the premium of insurance on the lives of the persons named in the grant of the annuities. Mr Onslow, in his speech on the usury laws, 23d of May 1816, mentions that he knew the case of a gentleman possessed of a very large estate in *fee-simple*, who had been compelled to grant an annuity for *four* lives (and the survivor of them), named by the grantee, for *eight* years' purchase.

House of Commons' Report on the Usury Laws.

The Report of the Committee on the Usury Laws, laid before the House of Commons in 1818, contains much valuable evidence, establishing the impolicy and the pernicious effects of these laws in the clearest manner. Mr Sugden, a gentleman very extensively concerned in the management of landed property, stated, that when the market rate of interest rose above the legal rate, the landed proprietor was compelled to resort to some shift to evade the usury laws. For this purpose, Mr Sugden informed the committee he had "known annuities granted for *three* lives, at ten per cent. upon fee-simple estates, unencumbered, and of great annual value, in a register county. He had also known annuities granted for *four* lives, and more would have been added, but for the danger of equity setting aside the transaction on account of the inadequacy of the consideration. Latterly many annuities were granted for a term of years certain, not depending upon lives." On being asked whether, if there were no laws limiting the rate of interest, better terms could or could not have been obtained, Mr Sugden answered, "I am decidedly of opinion that *better terms* could have been obtained; for there is a stigma which attaches to men who lend money upon annuities, that drives all respectable men out of the market. Some leading men did latterly embark in such transactions, but I never knew a man of reputation in my own profession lend money in such a manner, although we have the best means of ascertaining the safest securities, and of obtaining the best terms. In all loans, two solicitors are invariably concerned, one for the borrower and one for the lender; and although the borrower always pays the expense of the securities, yet a regular professional bill is invariably made out; whereas, in the case of an annuity, although it is in strictness a loan, only one solicitor is employed, and he never makes out a regular bill, but charges what is termed a *lumping sum*, for all his expense and trouble in the transaction." And, in another place, Mr Sugden observes, "the temptation on the part of a solicitor to lend money upon annuities is very strong, because, *without any check upon his charges, he demands whatever sum he pleases, and he takes care that it is instantly paid; for in no instance is the borrower allowed to leave the room until he has paid the solicitor's charge.*" "Nothing," Mr Sugden justly adds, "short of *a repeal of the usury laws* can put a stop to the abuses which attend grants of annuities: they strongly encourage a spirit of gambling; for, as the repayment of the money lent cannot be enforced, and the annuity is granted upon a contingency, the borrower too frequently neglects to provide for the payment of the loan, and trusts to chance for the determination of the annuity."

"The laws against usury," says Mr Holland, partner of the house of Baring, Brothers, and Company, and one of the best informed merchants in the country, "drive men in distress, or in want of money, to much more disastrous modes of raising it than they would adopt if no usury laws existed. The landowner requires capital to increase his live stock, or improve his land, or for any other purpose, at a period when the government is borrowing money at above five per cent., or when the funds give a greater interest than five per cent.; no one will then lend to the landowner, because his money is worth more to him than the law allows him to take; the landowner must, therefore, either give up his improvements, or borrow money on annuity interests, on much more disadvantageous terms than he could have done if no law existed against usury. The man in trade, in want of money for an unexpected demand, or disappointed in his returns, must fulfil his engagements, or forfeit his credit. He might have borrowed money at six per cent., but the law allows no one to lend it to him, and he must sell some of the commodity he holds, at a reduced price, in order to meet his engagements. For example, he holds sugar which is worth 80s.; but he is compelled to sell it immediately for 70s. to the man who will give him cash for it, and thus actually borrows money at twelve and a half per cent., which, had the law allowed him, he might have borrowed from a money dealer at six per cent. It is known to every merchant, that *cases of this kind are common occurrences in every commercial town, and more especially in the metropolis.* A man in distress for money pays more interest, owing to the usury laws, than he would if no such laws existed; because now he is obliged to go to some of the disreputable money lenders to borrow, as he knows the respectable money lender will not break the laws of his country. The disreputable money lender knows that he has the *ordinary risk* of his debtor to incur in lending his money, and he has further to encounter the *penalty of the law*, for both of which risks the borrower must pay. If no usury laws existed, in common cases, and where a person is respectable, he might obtain a loan from the respectable money lender, who would then only have to calculate his ordinary risk, and the compensation for the use of his money."

Resolutions of the committee.

In every part of the appendix to the *Report*, we meet with equally conclusive evidence of the pernicious effects of the laws restraining the rate of interest. And the committee admitted the full force of this evidence, by agreeing to the following resolutions: 1*st*, "That it is the opinion of this committee, that the laws regulating or restraining the rate of interest have been extensively evaded, and have failed of the effect of imposing a maximum on such rate; and that, of late years, from the constant excess of the market rate of interest above the rate limited by law, they have added to the expense incurred by borrowers on real security, and that such borrowers have been compelled to resort to the mode of granting annuities on lives; a mode which has been made a cover for obtaining a higher rate of interest than the rate limited by law, and has farther subjected the borrowers to enormous charges, or forced them to make very disadvantageous sales of their estates. 2*d*, That it is the opinion of this committee, that the construction of such laws, as applicable to the transactions of commerce as at present carried on, have been attended with much uncertainty as to the legality of many transactions of frequent occurrence, and consequently been productive of much embarrassment and litigation. 3*d*, That it is the opinion of this committee, that the present period, when the market rate of interest is below the legal rate, affords an opportunity peculiarly favourable for the repeal of the said laws."

In spite, however, of the recommendation of the committee, and of the clear and satisfactory nature of the evidence on which it is founded, the popular prejudice on this subject continues so strong, that there does not seem much reason to expect that this desirable measure will be speedily effected.

Pernicious effects of laws.

It is most absurdly supposed, that, were the laws limiting the rate of interest repealed, every individual who has

Interest.

capital to lend would henceforth indulge in all those mean and disgraceful practices which at present characterise the lowest class of money brokers. But it might just as reasonably be supposed, that were country gentlemen allowed to sell game, they would immediately become addicted to all the vices of the poacher. The truth is, that if the rate of interest was left to be adjusted by the unrestricted competition of the parties, there would be almost no employment for the inferior class of money dealers. Except when the *market* rate of interest is below the *legal* rate, the usury laws prevent all persons, whose credit is not extremely good, from obtaining loans from capitalists of the highest character, and force them to have recourse to those who are less scrupulous. Supposing the market rate of interest to be six or seven per cent., an individual in ordinarily good credit might, were the usury laws abolished, easily obtain a loan at that rate. But the law having declared that no more than five per cent. shall be taken, and consequently having affixed a species of stigma to those lenders who bargain for a higher rate, necessarily excludes the rich and more respectable capitalists from the market, and obliges borrowers to resort to those of an inferior character, who, in addition to the premium for the risk incurred by entering into an illegal transaction, must receive an indemnification for the *odium* which, in such cases, always attaches to the lender. It is idle and ridiculous to attempt to secure individuals against the risk of imposition in pecuniary, more than in any other species of transactions. But although the object were really desirable, it could not possibly be obtained by such inadequate means. The usury laws generate the very mischief they are intended to suppress. Far from diminishing, they most unquestionably multiply usurious transactions in a tenfold proportion, and powerfully aggravate all the evils they were designed either to mitigate or remove.

Nothing can be more unreasonable, or more entirely unfounded, than the clamour that has been set up against usurers, as money-lenders are sometimes termed, because of their exacting a higher rate of interest than ordinary from prodigals and spendthrifts. This, surely, is the most proper and efficient check that can be put upon the thoughtless or unprincipled extravagance of such persons. Supposing the security of a prodigal and of an industrious man to be nearly equal, and this can scarcely ever be the case, does not the capitalist who would lend to the latter at a lower rate of interest than he would lend to the former, confer a real service on his country? Does he not prevent those funds which ought to be employed in supporting useful labour, and in adding to the real wealth of the nation, from being wasted in ridiculous extravagances or boisterous dissipation?

They do not protect the prodigal and unwary.

But, perhaps, we shall be told, that this is mistaking the object of the usury laws; that they were not intended to force capitalists to lend to spendthrifts at the same rate of interest as to industrious persons, but to protect the prodigal and unwary from the extortion of usurers, by declaring any stipulation between them for more than a given rate of interest to be null and void. But why all this solicitude about the least valuable class of society? Why fetter and restrict the free circulation of capital amongst those who would turn it to the best account, lest any portion of it might chance to fall into the hands of those who would squander it away? If the prevention of prodigality be an object of sufficient importance to justify the interference of the legislature, why not at once put the prodigal under an *interdict?* This is the only way in which it is possible to restrict him. It is not so much by borrowing money at high interest, as by contracting debts to merchants, on whose charge there is no check, that spendthrifts generally run through their fortunes. Mr Bentham has justly observed, that so long as a man is looked upon as one who will pay, he can much easier get the goods he wants than he could the money to buy them with, though he were content to give for it twice or thrice the ordinary rate of interest. How ridiculous is it, then, to stimulate this natural facility of purchasing, to permit prodigals to borrow (for it is really borrowing) the largest supplies of food, clothes, &c. at twenty, thirty, or even a hundred per cent. interest, at the same time that we inflict a real injury on every other class of society, rather than permit them to borrow the smallest supply of money at more than five per cent. Instead of being of any service, this restriction is evidently injurious to the prodigal. It narrows his choice, and drives him from a market which might have proved much less disadvantageous, to one in which no disgrace attaches to the exaction of the most exorbitant interest, and where he can scarcely escape being ruined.

Neither is the outcry raised against capitalists for taking advantage of the necessities of industrious individuals, in any degree better founded than that which is raised against them for taking advantage of the extravagant and thoughtless disposition of the prodigal or the simple. According as a person has a character for sobriety, and for punctuality in making his engagements, and according to the presumed state of his affairs at the time, so will he be able to borrow. To say that a capitalist took advantage of the necessities of any individual, is only saying that he refused to lend to a person in suspicious or necessitous circumstances, at the same rate of interest he would have done had he been in high credit, or, which is the same thing, had there been no *risk* of losing the principal; and had he not acted in this manner, should we not have justly considered him as a fool or a madman?

But, as has already been shown, whatever may be the extortion of lenders, the usury laws afford no means of checking it; on the contrary, they compel the borrowers to pay, over and above the common rate of interest, a *premium* sufficient to indemnify the lender for the risk and odium incurred in *breaking them.* They attempt to remedy what is not an evil, and what, consequently, ought not to be interfered with; and in doing this they necessarily create a real grievance. What should we have thought of an act of parliament to compel the underwriters to insure a gunpowder magazine and a salt warehouse on the same terms? Yet this would not have been in any respect more absurd than to enact that the same rate of interest should be charged on capital lent to those whose security is widely different.

There were no usury laws in Holland.

Luckily we are not left to infer from general principles, however well established, the many advantages that would result from a repeal of the laws limiting the rate of interest. The case of Holland furnishes a practical and striking proof of the correctness of the theory we have been endeavouring to establish. It is an undoubted fact, that the rate of interest has been, for a very long period, lower in Holland than in any other country in Europe; and yet Holland is the only country in which usury laws are altogether unknown, where capitalists are allowed to demand, and borrowers to pay, any rate of interest.[1] Notwithstanding all the violent changes of the government, and the extraordinary derangement of her financial concerns in

[1] Strictly speaking, this applies only to the state of Holland previously to the Revolution in 1795. The enactments of the Code Napoleon were subsequently introduced; but it appears, from the Report of the Parliamentary Committee on the Usury Laws, that they have not, in any instance, been acted upon.

Interest.

the course of the last twenty years, the rate of interest in Holland has continued comparatively steady. During the whole of that period, persons who could offer unexceptionable security have been able to borrow at from three to five and a half per cent.; nor has the average rate of interest charged on capital, advanced on the worst species of security, ever exceeded six or seven per cent., except when the government was negotiating a forced loan.[1] But, in this country, where the law declares that no more than five per cent. shall be taken, the rate of interest for capital advanced on the best landed security has, in the same period, varied from five to sixteen or seventeen per cent., or *five* times as much as in Holland. Surely this ought to put to rest all doubts as to the impolicy and the inefficiency of the usury laws.

Legal rate of interest in France;

In France the usury laws were abolished at the Revolution; and it is distinctly stated, that their abolition *was not attended by any rise of interest.*[2] According to the *Code Napoleon*, only six per cent. interest is allowed to be taken in commercial affairs, and five per cent. when money is advanced on the security of real property. There is not, however, any difficulty in evading this law. The method resorted to for this purpose, is to give a *bonus* before completing the transaction, or, which is the same thing, to frame the obligation for the debt for a larger sum than was really advanced by the lender. None of the parties particularly interested can be called to swear to the fact of such a *bonus* being given; so that the transaction is unimpeachable, unless a third party, who was privy to the settling of the affair, can be produced as a witness. The Bank of France never discounts at a higher rate of interest than five per cent., but sometimes at a lower rate.

In Hamburg;

In Hamburg the rate of interest is quite unrestricted; or, if there be a written law restraining it, it has become altogether obsolete. The rate, therefore, varies according to circumstances. Occasionally it has been at seven, eight, and even ten per cent.; and, in 1799, a period of great mercantile embarrassment and insecurity, it was as high as fourteen per cent. Generally, however, the rate of discount on good bills does not exceed four or five per cent.[3]

In Russia;

In Russia the legal rate of interest is six per cent. But as Russia is a country capable of much improvement, and where there are very great facilities for the advantageous employment of capital, the market rate of interest is invariably higher than the statute rate, and the law is as constantly as it is easily evaded.[4]

In Austria;

At Trieste, and throughout the Austrian empire in general, the usual rate of interest is fixed by law at six per cent.; but capital can seldom be obtained for less than eight or ten per cent.[5]

In Leghorn;

At Leghorn the ordinary rate of interest is a half per cent. per month, or six per cent. per annum; but there is no law to prevent the taking of a higher rate.

In Spain;

In Spain the ordinary rate of interest is six per cent.; but no law exists against taking a higher rate, and it seldom falls below five or rises above seven per cent.

In the United States.

In the United States legal interest is fixed at six per cent.; but the market rate fluctuates from ten to twelve per cent. Efforts, Mr Birkbeck informs us, are now making in various parts of the Union, particularly in Virginia and North Carolina, to do away the restraints on usury, which, as he justly observes, "*operate merely as a tax on the needy borrower.*"[6]

Usury laws do not reach the government.

If usury laws are to have any existence, they ought certainly to be made to operate on the greatest of all borrowers; on those who do not borrow on their own credit, but on that of others. Is it not the extreme of folly, that, whilst an industrious manufacturer, or agriculturist, is prevented from giving more than five per cent. for capital, which he might be able to invest so as to yield ten or twelve per cent., government should be allowed to borrow at six, eight, ten, or twenty per cent.? What is this but holding out a bait to loan-mongers, and causing the capital of the country to flow with an accelerated and unnatural velocity into the treasury? Nothing surely can be more impolitic than this. If we are to have usury laws, they ought to operate alike on every class of borrowers; and, considering the superior attractions which the facility of repossessing the principal gives to the investment of capital in the funds, the rate of interest at which government should be allowed to borrow should be *less* than the rate at which private individuals might borrow.

We trust, however, that we have said enough to show the inexpediency and the pernicious tendency of all such regulations. If a landlord is to be allowed to take the highest rent he can get offered for his land, a farmer the highest price for his raw produce, a manufacturer for his goods, why should a capitalist be restricted and fettered in the employment of his stock? Every principle of natural justice, and of sound political expediency, is outraged by such a distinction.

So long as the market rate of interest continued higher than the statutory rate, it cannot be doubted that considerable inconvenience would have resulted from any *sudden* abolition of the usury laws. It is certain, indeed, that this inconvenience would have been very speedily compensated by the check which the abolition would have given to the traffic in annuities, and by the easier circulation and more advantageous distribution of capital. Now, however, when the market is fallen below the statutory

---

[1] The general rate of discount in Holland is from four to five per cent., and occasionally from three to three and a half per cent., but very seldom lower. During the Revolution it had been at six and seven per cent., and even at eight; but this was generally owing to some *forced financial operation* on account of the government, and was never of long duration. The following is the average rate of discount at Amsterdam and Rotterdam from 1795 to 1817:

1795—4, 4½, 5, 6.
1796—4, 4½, 5, 6.
1797—4, 4½, 5, 5½, 6, 9, 12.
1798—4, 4½, 5, 5.
1799—3, 4, 4½, 5.
1800—4, 4½, 5, 6.
1801—4, 4½, 5, 6.
1802—4½, 5, 5½, 6.
1803—4, 5, 5½, 6.
1804—4, 4½, 5, 5½, 6.
1805—4, 5, 5½, 6, 9.
1806—4, 4½, 5, 5½, 6, 9.
1807—4, 4½, 5, 6.
1808—4, 3½, 4½, 5, 6.
1809—4, 4½, 5, 6.
1810—4, 4½, 5, 6.
1811—3, 3½, 4, 5.
1812—3, 3½, 4, 5.
1813—3, 3½, 4, 5, 6.
1814—4, 5, 5½, 5, 6, 6½.
1815—5½, 6, 6½, 7.
1816—5, 5½, 6, 6½, 7.
1817—5, 5½, 6.

"The bank of Amsterdam never discounts at a higher rate than five per cent.; but they discount at a lower rate, and vary their discounts according to the abundance of capital, never exceeding five per cent., and occasionally as low as two and a half and three." (Mr Holland's evidence, *Report of the Committee on the Usury Laws*, p. 45.)

Interjection || Interim.

rate of interest, no inconvenience could attend their repeal. It could not lead to any demand for payment of borrowed money, for no individual would require payment of what he could not relend to greater advantage. But, while their repeal would be in no respect disadvantageous, it would enable those who are engaged in employments of more than ordinary hazard, to procure adequate supplies of stock on more favourable terms; and it would also secure us against the risk of future mischief should the market again rise above the legal rate of interest. It is unnecessary, however, to urge the *immediate* repeal of the usury laws. We think it quite visionary to apprehend any danger from the instant application of a sponge to the whole of the anti-usurious statutes, but it is enough if they are repealed *gradually*. To avoid exciting any alarm in the minds of the most timid, the rate at which capital may be legally lent at interest might be annually raised *one* or *one half* per cent., until the rate had been extended to eight or ten per cent., when it is clear every restrictive regulation might be abolished, without the possibility of the smallest derangement happening in consequence.

Were the usury laws abolished, it would be proper to frame a statute which should fix the interest to be paid in those cases in which no previous agreement had been made respecting it. But as, in cases of this description, there is very frequently considerable doubt whether it was the intention of the parties at the time the transaction took place, that any interest should be charged, it would be proper to give the borrower the full benefit of this doubt, by fixing the rate payable in such cases at the lowest market rate.

Error of some writers on the subject of a low rate of interest.

Before concluding, we may remark, that, until the laws regulating the rate of profit and the increase of capital had been accurately investigated, the great wealth and commercial prosperity of Holland was invariably appealed to as a practical proof of the advantages of a low rate of interest. But Sir Josiah Child, and those who have insisted so much on this example, forget that the lowness of interest in Holland was the necessary effect of the circumstances in which that country was placed; of the lowness of profits, caused by the oppressiveness of taxation, and the deficient supply of fertile soil, and not of any *interference* on the part of the government. Neither was this lowness of interest any advantage, but a positive disadvantage. A country, whose average rate of profit, and consequently of interest, has been reduced considerably below the level of surrounding nations, may, notwithstanding, abound in wealth, and be possessed of an immense capital; but it would be the height of error to suppose that this reduction of profits and interest could have facilitated their accumulation. Capital cannot be accumulated otherwise than by a saving of income; and wherever incomes are large, and this will always be the case where the rate of profit is comparatively high, there must be a proportionably increased facility of gratifying the prevalent passion for accumulation. The case of Holland, far from contradicting, furnishes a striking example of the truth of this principle. Sir William Temple mentions that her trade was rather on the decline in 1670; and the large capital of which she was then in possession had been accumulated previously to her wars with Cromwell, and when the rate of profit was much higher than at any subsequent period. Low profits are a certain proof that society has become clogged in its progress. They show that it is approaching, if it has not already reached, the stationary state, and that, unless measures can be devised for relieving the pressure on the resources of the state, it will be thrown back in the career of improvement, and outstripped by its neighbours. The rate of profit and the rate of interest are ordinarily twice as high in the United States as in Great Britain or France, and it is to this that the more rapid advancement of the former in wealth and population is entirely to be ascribed. High profits, it is true, may not in every instance be accompanied by a great degree of prosperity; for a despotic government, or the want of sufficient protection, may paralyze all the efforts of those who are otherwise placed in the most favourable circumstances for the accumulation of wealth. But, *if the government be equally liberal, and if property be equally well secured, the degree of national prosperity will be correspondent to the rate of profit.* The demand for labour, or, which is in effect the same thing, the funds for supporting the largest and most valuable portion of society, increase or diminish in exact proportion to the increase or diminution of profits. Wherever they are high, the labourer is well paid, and the society rapidly augments both its population and its riches; on the other hand, wherever they are low, the demand for labour is proportionably reduced, and the progress of society rendered so much the slower.

Instead, therefore, of a low rate of profit, and a low rate of interest, for the one must be always directly as the other, being any proof of the flourishing situation of a country, it is distinctly and completely the reverse. High profits show that capital may be readily and beneficially invested in the different branches of industry, and wherever this is the case, it will be better for the borrower to pay a high rate of interest than it would be for him to pay a lower rate, in countries where there is less facility of employing his stock with advantage. The borrower who pays ten or twelve per cent. for capital in the United States generally makes a more profitable bargain than the English borrower who pays only four or five per cent. It is obviously not by the circumstance of the rate of interest payable on loans being absolutely high or low, but by the proportion between that rate and the average rate of profit, that we must determine whether they have been obtained on favourable or unfavourable terms. (C. C.)

INTERJECTION, in *Grammar*, an indeclinable part of speech, expressive of some passion or emotion of the mind. See GRAMMAR.

INTERIM, a name given to a formulary, or kind of confession, of the articles of faith, obtruded upon the Protestants after Luther's death by the Emperor Charles V. when he had defeated their forces; and so called because it was only to take place in the *interim* (mean time), till a general council should have decided all points in dispute between the Protestants and Catholics. It retained most of the doctrines and ceremonies of the Catholics, excepting that of marriage, which was allowed to the clergy, and communion to the laity under both kinds. Most of the Protestants rejected it. There were two interims besides this; the one of Leipsic, and the other of Franconia.

INTERLOCUTOR, in *Scotch Law*, is the decision or judgment of a court before the final decree is passed and extracted.

INTERLOCUTORY DECREE, in *English Law*. In a suit in equity, if any matter of fact be strongly controverted, the fact is usually directed to be tried at the bar of the Court of King's Bench, or at the assizes, upon a feigned issue. If a question of mere law arises in the course of a cause, it is the practice of the Court of Chancery to refer it to the opinion of the judges of the Court of King's Bench, upon a case stated for that purpose. In such cases, interlocutory decrees or orders are made.

Interlocutory Judgments are such as are given in the middle of a cause, upon some plea, proceeding on default, which is not intermediate, and does not finally determine or complete the suit. But the interlocutory judgments most usually spoken of are those incomplete judgments by which the right of the plaintiff is established, but the quantum of damages sustained by him is not ascertained, which is the province of a jury. In such a case a writ of inquiry issues to the sheriff, who summons a jury, inquires of the damages, and returns to the court the inquisition so taken, whereupon the plaintiff's attorney taxes costs, and signs final judgment.

Interlocutory Order, that which decides not the cause, but only settles some intervening matter relating to the cause; as where an order is made in chancery, for the plaintiff to have an injunction to quit possession till the hearing of the cause. This order, not being final, is called *interlocutory*.

INTERLOPERS are properly those who, without due authority, hinder the trade of a company or corporation lawfully established, by dealing in the same way.

INTERLUDE, an entertainment exhibited on the theatre between the acts of a play, to amuse the spectators, or to give time for changing the scenes and decorations. In the ancient tragedy, the chorus sung the interludes, to show the intervals between the acts. Interludes, amongst us, usually consist of songs, dances, feats of activity, concerts of music, and the like. Aristotle and Horace lay it down as a rule, that the interludes should consist of songs founded on the principal parts of the drama; but since the chorus has been discontinued, dancers, buffoons, and such like performers, ordinarily furnish the interludes.

INTERMENT, the act of interring, that is, burying or laying a deceased person in the ground.

Aristotle asserted that it was more just to assist the dead than the living. Plato, in his Republic, does not forget, amongst other acts of justice, that which concerns the dead. Cicero establishes three kinds of justice; the first respects the gods, the second the manes or dead, and the third men. These principles seem to be derived from nature; and they appear at least to be necessary for the support of society, since civilized nations have at all times taken care to bury their dead, and to pay the last respects to their remains.

We find in history several traces of the respect which the Indians, the Egyptians, and the Syrians entertained for the dead. The Syrians embalmed their bodies with myrrh, aloes, honey, salt, wax, bitumen, and resinous gums; and they also dried them with the smoke of the fir and of the pine tree. The Egyptians preserved theirs with the resin of the cedar, with aromatic spices, and with asphaltum. These people often kept such mummies, or at least their effigies, in their houses; and at grand entertainments they were introduced, that by reciting the great actions of their ancestors they might be the more excited to virtue.

The Greeks, at first, had probably not the same veneration for the dead as the Egyptians. Empedocles, therefore, in the eighty-fourth Olympiad, restored to life Ponthia, a woman of Agrigentum, who was about to be interred. But this people, in proportion as they became more enlightened, perceived the necessity of establishing laws for the protection of the dead.

At Athens the law required that no person should be interred before the third day; and in the greater part of the cities of Greece a funeral did not take place till the sixth or even the seventh day. When a man appeared to have breathed his last, his body was generally washed by his nearest relations, with warm water mixed with wine. They afterwards anointed it with oil; and covered it with a dress commonly made of fine linen, according to the custom of the Egyptians. This dress was white at Messina, Athens, and in the greater part of the cities of Greece, where the dead body was crowned with flowers. At Sparta it was of a purple colour, and the body was surrounded with olive leaves. The corpse was afterwards laid upon a couch in the entry of the house, where it remained till the time of the funeral. At the magnificent obsequies with which Alexander honoured Hephæstion, the body was not burned until the tenth day.

Interment.

The Romans, in the infancy of their empire, paid as little attention to their dead as the Greeks had done. Acilius Aviola having fallen into a lethargic fit, was supposed to be dead; he was therefore carried to the funeral pile; the fire was lighted up; and though he cried out he was still alive, he perished for want of speedy assistance. The prætor Lamia met with the same fate. Tubero, who had been prætor, was saved from the funeral pile. Asclepiades, a physician, who lived in the time of Pompey the Great, about one hundred and twenty years before the Christian era, returning from his country-house, observed near the walls of Rome a grand convoy and a crowd of people, who were in mourning, assisting at a funeral, and showing every exterior sign of the deepest grief. Having asked what was the occasion of this concourse, no one made any reply. He therefore approached the pretended dead body; and imagining that he perceived signs of life in it, he ordered the bystanders to take away the flambeaux, to extinguish the fire, and to pull down the funeral pile. On this a kind of murmur arose throughout the whole company. Some said that they ought to believe the physician, whilst others turned both him and his profession into ridicule. The relations, however, yielded at length to the remonstrances of Asclepiades; they consented to defer the obsequies for a little; and the consequence was that the pretended dead person was restored to life. It appears that these examples, and several others of a similar kind, induced the Romans to delay funerals longer, and to enact laws to prevent precipitate interments.

At Rome, after allowing a sufficient time for mourning, the nearest relation generally closed the eyes of the deceased; and the body was bathed with warm water, either to render it fitter for being anointed with oil, or to re-animate the principle of life, which might remain suspended without manifesting itself. Proofs were afterwards made to discover whether the person was really dead, and these were often repeated during the time that the body remained exposed; for there were persons appointed to visit the dead, and to prove their situation. On the second day, after the body had been washed a second time, it was anointed with oil and balm. Luxury increased to such a pitch in the choice of foreign perfumes for this purpose, that under the consulship of Licinius Crassus and Julius Cæsar, the senate forbade any perfumes to be used except such as were the production of Italy. On the third day the body was clothed according to its dignity and condition. The robe called the *prætexta* was put upon magistrates, and a purple robe upon consuls. For conquerors who had merited triumphal honours, this robe was of gold tissue; for other Romans it was white, and for the lower classes of the people black. These dresses were often prepared at a distance, by the mothers and wives of persons still in life. On the fourth day the body was placed on a couch, and exposed in the vestibule of the house, with the visage turned towards the entrance, and the feet near the door; and in this situation it remained till the end of the week. Near the couch were lighted wax-tapers, a small box in which perfumes were burned, and a vessel full of water for purification, with which those who approached the body besprinkled

Interment. themselves. An old man belonging to those who furnished every thing necessary for funerals sat near the deceased, with some domestics clothed in black. On the eighth day the funeral rites were performed; but, to prevent the body from corrupting before that time, salt, wax, the resinous gum of the cedar, myrrh, honey, balm, gypsum, lime, asphaltum or bitumen of Judæa, and several other substances, were employed. The body was carried to the pile with the face uncovered, unless wounds, or the nature of the disease, had rendered it loathsome and disgusting. In such a case a mask was used, made of a kind of plaster, which has given rise to the expression of *funera larvata,* used in some of the ancient authors. This was the last method of concealment which Nero made use of, after having caused Germanicus to be poisoned; for the effect of the poison had become very sensible, by livid spots, and the blackness of the body; but a shower of rain happening to fall, it washed the plaster entirely away, and thus the horrid crime of fratricide was discovered.

In the primitive church the dead were washed and then anointed; the body was wrapped up in linen, or clothed in a dress of more or less value according to circumstances, and it was not interred until after being exposed and kept some days in the house. The custom of clothing the dead is in France observed only in the case of princes and ecclesiastics.

Notwithstanding the customs above recited, still, in many places, and on numerous occasions in all places, too much precipitation attends this last office; or, if not precipitation, a neglect of due precautions in regard to the body.

A man may fall into a syncope, and remain in that condition for a very considerable period of time. People in this situation have been known to come to life when deposited amongst the dead. A boy belonging to the hospital at Cassel appeared to have breathed his last; he was carried into the hall where the dead were exposed, and was wrapped up in a piece of canvass. Some time afterwards, recovering from his lethargy, he recollected the place in which he had been deposited, and crawling towards the door, knocked against it with his foot. This noise was luckily heard by the sentinel, who soon perceiving the motion of the canvass, called for assistance. The youth was immediately conveyed to a warm bed, and soon perfectly recovered. Had his body been confined by close bandages or ligatures, he would not have been able, in all probability, to make himself be heard; his unavailing efforts would have made him again fall into a syncope, and he would have thus been buried alive.

We must not be astonished that the servants of an hospital should take a syncope for a real death, since even the most enlightened persons have sometimes fallen into errors of the same kind. Dr John Schmid relates, that a young girl, seven years of age, after being afflicted for some weeks with a violent cough, was all of a sudden freed from this troublesome malady, and appeared to be in perfect health. But some days afterwards, whilst playing with her companions, the child fell down in an instant, as if struck by lightning. A death-like paleness was diffused over her face and arms; she had no apparent pulse, her temples were sunk, and she showed no signs of sensation when shaken or pinched. A physician, who was called, and who believed her to be dead, in compliance with the repeated and pressing request of her parents, attempted, though without any hopes, to recall her to life; and at length, after several vain efforts, he made the soles of her feet be smartly rubbed with a brush dipped in very strong pickle. At the end of three quarters of an hour she was observed to sigh; she was then made to swallow some spirituous liquor; and she was soon afterwards restored to life, much to the joy of her disconsolate parents. A certain man having undertaken a journey in order to see his brother, on his arrival at his house found him dead. This news affected him so much that it brought on syncope, and he himself was supposed to be in the like situation. After the usual means had been employed to recall him to life, it was agreed that his body should be dissected, to discover the cause of so sudden a death; but the supposed dead person overhearing this proposal, opened his eyes, started up, and immediately betook himself to his heels. Cardinal Espinola, prime minister to Philip II. was not so fortunate; for, in the memoirs of Amelot de la Houssai, we are informed that he put his hand to the knife with which he was opened in order to be embalmed. In short, almost every one knows that Vesalius, the father of anatomy, having been sent for to open the body of a woman subject to hysterics, who was supposed to be dead, he perceived, on making the first incision, that she was still alive; that this circumstance rendered him so odious, that he was obliged to fly; and that he was so much affected by it, that he died soon afterwards. On this occasion we cannot forbear adding an event more recent, but not less melancholy. The Abbé Prevost, so well known by his writings and the singularities of his life, was seized with a fit of apoplexy, in the forest of Chantilly, on the 23d of October 1763. His body was carried to the nearest village, and the officers of justice were proceeding to open it, when a cry which he sent forth terrified all the assistants, and convinced the surgeon that the abbé was not dead; but it was too late to save him, as he had already received a mortal wound.

We shall conclude this article by subjoining, from Dr Hawes's *Address to the Public,* a few of the cases in which this fallacious appearance of death is most likely to happen, together with the respective modes of treatment which he recommends.

In apoplectic and fainting fits, and in those arising from any violent agitation of mind, and also when opium or spirituous liquors have been taken in too great quantity, there is reason to believe that the appearance of death has been frequently mistaken for the reality. In these cases, the means recommended by the *Humane Society for the Recovery of Drowned Persons* should be persevered in for several hours; and bleeding, which in similar circumstances has sometimes proved pernicious, should be used with great caution. In the two latter instances it will be highly expedient, with the view of counteracting the soporific effects of opium and spirits, to convey into the stomach, by a proper tube, a solution of tartar emetic, and by various other means to excite vomiting.

From the number of children carried off by convulsions, and the certainty arising from undoubted facts that some who have in appearance died from that cause have been recovered, there is the greatest reason for concluding, that many, in consequence of this disease, have been prematurely numbered amongst the dead; and that the fond parent, by neglecting the means of recalling life, has often been the guiltless executioner of her own offspring. To prevent the commission of such dreadful mistakes, no child whose life has been apparently extinguished by convulsions should be consigned to the grave till the means of recovery above recommended have been tried, and, if possible, under the direction of some skilful practitioner of medicine, who may vary them as circumstances seem to require.

When fevers arise in weak habits, or when the cure of these has been principally attempted by means of depletion, the consequent debility is often very great, and the patient sometimes sinks into a state which bears so close an affinity to that of death, that there is reason to suspect it has too often deceived the bystanders, and induced them to send for the undertaker when they should have had recourse to the succours of medicine. In such cases, volatiles, *eau de luce*, for example, should be applied to the nose, rubbed on the temples, and sprinkled about the bed; hot flannels, moistened with a strong solution of camphorated spirit, may likewise be applied over the breast, and renewed every quarter of an hour; and, as soon as the patient is able to swallow, a teaspoonful of the strongest cordial should be given every five minutes.

The same methods may also be used with propriety in the small-pox, when the pustules sink, and death apparently ensues; and likewise in any other acute diseases, when the vital functions are suspended from a similar case.

INTERMITTENT or INTERMITTING FEVER, such fevers as go off and soon return again, in opposition to those which are continual.

INTERPOLATION, amongst critics, denotes a spurious passage inserted into the writings of some ancient author.

INTERPOLATION, in the modern algebra, signifies to find an intermediate term of a series, its place in the series being given. This method was first invented by Mr Briggs, and applied by him to the calculation of logarithms.

INTERPOSITION, the situation of a body between two others, so as to hide them, or prevent their action.

The eclipse of the sun is occasioned by an interposition of the moon between the sun and the earth; and that of the moon by the interposition of the earth between the sun and moon.

INTERPRETER, a person who explains the thoughts, words, or writings, of some other. The word *interpres*, according to Isidore, is composed of the preposition *inter*, and *partes*, as signifying a person in the middle between two parties, to make them mutually understand each other's thoughts; whilst others derive it from *inter*, and *præs*, *fidejussor*, that is, a person who serves as security between two others who do not understand each other.

There have been many and keen debates about interpreting Scripture. The Catholics contend that it belongs absolutely to the church; adding, that where she is silent, reason may be consulted, but where she speaks, reason is to be disregarded. The Protestants generally allow reason to be the sovereign judge or interpreter, though some amongst them have a strong regard to synods, and others to the authority of the primitive fathers. Lastly, there are those who have recourse to the spirit within every person to interpret for them, which is what Bochart calls ἀποδειξις του πνευματος.

INTERREGNUM, the time during which the throne is vacant in elective kingdoms; seeing that, in such as are hereditary, like ours, there is no such thing as an interregnum.

INTERREX, the magistrate who governs during an interregnum. This magistrate was established in ancient Rome, and was almost as old as the city itself. After the death of Romulus there was an interregnum of a year, during which the senators were interreges in their turn, five days each.

After the establishment of consuls and of a commonwealth, though there were no kings, yet the name and function of *interrex* was still preserved; for, when the magistrates were absent, or there was any irregularity in their election, or they had abdicated, so that the comitia could not be held, provided they were unwilling to create a dictator, they made an interrex, whose office and authority lasted five days, and after this they appointed another. To the interrex was delegated all the regal and consular authority, and he performed all their functions. He assembled the senate, held comitia or courts, and took care that the election of magistrates was made according to rules. Indeed at first it was not the custom of the interrex to hold comitia, at least we meet with no instance of it in the Roman history. The patricians alone had the right of electing an interrex; but this office fell with the republic, when the emperors made themselves masters of everything.

INTERROGATION, EROTESIS, a figure of rhetoric, in which the passion of the speaker introduces a thing by way of interrogation, to make its truth more conspicuous.

The interrogation is a kind of apostrophe which the speaker makes to himself; and it must be owned that this figure is suited to express most passions and emotions of the mind, and that it serves also to press and bear down an adversary, and generally adds an uncommon briskness, action, force, and variety, to discourse.

INTERROGATION, in *Grammar*, is a point which serves to distinguish those parts of a discourse, where the author speaks as if he were asking questions. Its form is this (?).

INTERSCENDENT, in *Algebra*, is applied to quantities, when the exponents of their powers are radical quantities. Thus, $x^{\sqrt{2}}$, $x^{\sqrt{a}}$, &c. are interscendent quantities.

INTERSECTION, in *Mathematics*, the cutting of one line or plane by another; or the point or line in which two lines or two planes cut each other.

The mutual intersection of two planes is a right line. The centre of a circle is in the intersection of two diameters. The central point of a regular or irregular figure of four sides, is the point of intersection of the two diagonals.

The equinoxes happen when the sun is in the intersections of the equator and ecliptic.

INTERVAL, the distance or space between two extremes, either in time or in place. The word comes from the Latin *intervallum*, which, according to Isidore, signifies the space *inter fossam et murum*, between the ditch and the wall; whilst others observe that the stakes or piles driven into the ground in the ancient Roman bulwarks were called *valla*, and the interstices or vacant spaces between them *intervalla*.

INTERVAL, in *Music*. The distance between any given sound and another, strictly speaking, is not measured by any common standard of extension or duration, but either by immediate sensation, or by computing the difference between the numbers of vibrations produced by two or more sonorous bodies, in the act of sounding, during the same given time. As the vibrations are slower and fewer during the same instant, the sound is proportionally lower or graver; and, on the contrary, as during the same period the vibrations increase in number and velocity, the sounds are proportionally higher or more acute. An interval in music, therefore, is properly the difference between the number of vibrations produced by one sonorous body of a certain magnitude and texture, and of those produced by another of a different magnitude and texture, in the same time.

Intervals are divided into consonant and dissonant. A consonant interval is that whose extremes, or whose highest and lowest sounds, when simultaneously heard, coalesce in the ear, and produce an agreeable sensation called by Lord Kames a *tertium quid*. A dissonant interval, on the contrary, is that whose extremes, simultaneously heard, far from coalescing in the ear, and producing one agreeable sensation, are each of them plainly distinguishable from the other, produce a grating effect upon the sense, and repel each other with an irreconcileable hostility. In proportion as the vibrations of different sonorous bodies, or of the same sonorous body in different modes, more or less frequently coincide during the same given time, the chords are more or less consonant. When these vibrations never coincide at all in the same given time, the discord is consummate, and consequently the interval absolutely dissonant. For a full account of these, see MUSIC.

INTESTATE, in *Law*, a person who dies without making a will.

INTONATION, in *Music*, the action of sounding the notes in the scale with the voice, or any other given order of musical tones. Intonation may either be true or false, too high or too low, too sharp or too flat; and then this word *intonation*, attended with an epithet, must be understood concerning the manner of performing the notes.

In executing an air, to form the sounds, and preserve the intervals as they are marked, with justness and accuracy, is no inconsiderable difficulty, and scarcely practicable, but by the assistance of one common idea, to which, as to their ultimate test, these sounds and intervals must be referred. These common ideas are those of the key, and the mode in which the performer is engaged; and from the word *tone*, which is sometimes used in a sense almost identical with that of the key, the word *intonation* may perhaps be derived. It may also be deduced from the word *diatonic*, as in that scale it is most frequently conversant; a scale which appears most convenient and natural to the voice. We feel more difficulty in our intonation of such intervals as are greater or less than those of the diatonic order; because, in the first case, the *glottis* and vocal organs are modified by gradations too large; or too complex, in the second.

INTRENCHMENT, in the military art, is any work which fortifies a post against the attack of an enemy. It is generally taken for a ditch or trench with a parapet. Intrenchments are sometimes made of fascines with earth thrown over them, or of gabions, hogsheads, or bags filled with earth, to cover the men from the enemy's fire.

INTRIGUE, an assemblage of events or circumstances occurring in an affair, and perplexing the persons concerned in it. In this sense it is used to signify the *nodus* or plot of a play or romance; or that point in which the principal characters are most embarrassed, through the artifice and opposition of certain persons, or the unfortunate falling out of certain accidents and circumstances.

INTRASCA, a city of the kingdom of Sardinia, in the province Pallanza, on Lake Maggiore, containing a nunnery, two churches, 320 houses, and 4570 inhabitants. Here are considerable manufactures of linen goods, hats, glass, and other wares.

INTRINSIC, a term applied to the real and genuine values and properties of any thing, in opposition to their *extrinsic* or *apparent* qualities.

INTRODUCTION, in general, signifies any thing which tends to make another in some measure known, before we have leisure or proceed to examine it thoroughly; and hence it is used on a great variety of occasions. The term is also used to signify the actual motion of any body out of one place into another, when that motion has been occasioned by some other body.

INTUITION, amongst logicians, the act by which the mind perceives the agreement or disagreement of two ideas, immediately by themselves, without the intervention of any other; in which case the mind perceives the truth as the eye does the light, only by being directed towards it. See METAPHYSICS.

INTUITIVE EVIDENCE is that which results from intuition. Dr Campbell distinguishes different sorts of *intuitive* evidence; one resulting purely from intellection, another kind arising from consciousness, and a third sort from that faculty called common sense, which this ingenious writer contends to be a distinct original source of knowledge; but others refer its supposed office to be *intuitive* power of the understanding.

INUNDATION, a sudden overflowing of the dry land by the waters of the ocean, rivers, lakes, springs, or rains.

INVALID, a person wounded, maimed, or disabled for action by age.

INVECTED, in *Heraldry*, denotes a thing fluted or furrowed. See HERALDRY.

INVECTIVE, in *Rhetoric*, differs from reproof, as the latter proceeds from a friend, and is intended for the good of the person reproved; whereas invective is the work of an enemy, and entirely designed to vex and give uneasiness to the person against whom it is directed.

INVENTION denotes the art of finding any thing new, or even the thing thus found. Thus we say, *the invention of gunpowder*, *the invention of printing*, and so on.

INVENTION is also used for the finding of a thing hidden. The Roman Catholic church celebrates a feast on the 4th of May, under the title of the invention of the holy cross.

INVENTION is also used for subtilty of mind, or something peculiar to a man's genius, which leads him to discover things new; in which sense we say, *a man of invention*.

INVENTION, in *Painting*, is the choice which the painter makes of the objects that are to enter into the composition of his piece.

INVENTION, in *Poetry*, is applied to whatever the poet adds to the history of the subject he has chosen, as well as to the new turn he gives it.

INVENTION, in *Rhetoric*, signifies the finding out and choosing of certain arguments which the orator is to use for proving or illustrating his point, moving the passions or conciliating the minds of his hearers. Invention, according to Cicero, is the principal part of oratory; and he wrote four books *De Inventione*, of which we have but two remaining.

INVERARY, a royal burgh of Scotland, and capital of the county of Argyle. It is delightfully situated on the west bank of Loch Fine, near its upper extremity, at the distance of 102 miles west by north of Edinburgh, 60 north-west from Glasgow, and thirty to the south-east of Oban. In front of the town is the small bay of Loch Fine, environed by romantic and woody hills; whilst, on its north side, with extensive and beautiful pleasure-grounds, stands the castle of Inverary, the seat of the ducal house of Argyle. Behind this spacious mansion the river Ary joins the loch, and from its margin rises the pyramidal hill of Duinicoich, to an elevation of seven hundred feet, embellished and wooded to the summit. The town of Inverary is small, consisting principally of a line of houses facing the lake. The town originally stood on the north side of the bay, but was removed by the proprietor to its present site. Within these few years several elegant residences have been erected, and the houses are generally well built. The town possesses a very comfortable modern church, a jail and court-house, with a parish, grammar, and charity school; the two latter being supported by the Argyle family. The herring fishery is the chief trade carried on here; and for the convenience of maritime traffic there is a well-built quay, which projects so far into the bay as to admit of vessels of considerable burden loading and unloading at low water. Inverary was an early seat of the Argyle family, under whose influence it was created a royal burgh by Charles I. in 1648, during his residence at Caresbrook Castle. By this arrangement its civic government consists of a provost, two bailies, a dean of guild, a treasurer, and a council appointed by the duke. The revenue arises from the petty customs, the rent of a common, and an annuity of L.20 conferred upon it by Duke Archibald. The castle is the principal object of attraction in this part of the county. It is a square edifice, built to replace one of more ancient date, and is constructed with a tower at each corner. The scenery around this elegant mansion attracts universal admiration, and the decorations of the interior of the building are of corresponding splendour. The collection of old Highland armour which is to be found within the saloon, is particularly worthy of attention. No less than L.30,000 are said to have been expended in building, planting, improving, making roads, and in other works or utility and decoration in and around the castle. During summer Inverary is resorted to by an immense number of travellers. It can be approached from Glasgow by three routes, all of which are more or less calculated to delight the lover of the sublime or beautiful in nature. First, there are steam-boats which sail down the Clyde, touching at Greenock and Rothesay, then through the tortuous and beautiful strait called the Kyles of Bute, and finally up the long arm of the sea called Loch Fine, near the head of which Inverary is situated. The second route is more direct, and occupies only about one half the time of the former. After passing down the Clyde, a small arm of the sea called Holy Loch is entered; and the traveller, after disembarking at the small village of Kilmun, crosses a wild vale of a few miles in length, and then enters upon the beautiful inland lake called Loch Eck, at the top of which he is transferred over land to the shores of Loeh Fine. The third route involves the famous scenery of Loch Lomond and Glencoe, and is somewhat more circuitous than that just mentioned. By all these routes, scenery combining the grand with the beautiful is opened up to the eye of the tourist. The population of the town and parish amounted in 1821 to 1137, and in 1831 to 2133.

INVERBERVIE, or Bervie, a town of Scotland, in Kincardineshire, and a royal burgh in virtue of a charter of David II. dated 1362, and renewed by James VI. in 1595. It is situated on the sea-coast, at the mouth of a stream called Bervie, between two small hills, which terminate in high cliffs towards the sea, at thirteen miles distance north-east from Montrose. The first machine for spinning flax in Scotland was erected at Bervie, which still carries on this manufacture to an inconsiderable extent. It unites with Montrose, Arbroath, Brechin, and Forfar, in returning a member to parliament. In 1831 the population amounted to 1137.

INVERKEITHING, a royal burgh of Scotland, in the county of Fife, is agreeably situated in a bay called St Margaret's Hope, on the north shores of the Frith of Forth, at the distance of thirteen miles from Kirkaldy, twenty-eight from Stirling, four from Dunfermline, and about fourteen from Edinburgh. It stands on the brow of an acclivity which rises from the margin of the bay, and consists of one main street of considerable length, with diverging lines and thoroughfares, and a number of houses erected in the neighbourhood of the harbour. Inverkeithing is a town of very considerable antiquity. The first existing grant which it possesses is one from William the Lion, confirming one of an earlier but unknown date, by which grant the burgh was endowed with a jurisdiction over the adjacent county to an extent of at least twenty miles each way. Within these limits the civic authorities possessed considerable powers and privileges, some of which remain to this day. James VI. confirmed the writ of the burgh in 1598. The civic government is exercised by a provost and high sheriff, two bailies, a dean of guild, and treasurer, annually elected by the councillors and deacons of the trades. This town, in times of remote antiquity, is said to have been the residence of many noble families; and David I. is known to have had a minor palace here. An old antique tenement is also pointed out as having been the abode of Queen Annabella Drummond, the consort of Robert III. and mother of the first James. Before Edinburgh obtained the honour, Inverkeithing was the place where the convention of royal burghs was regularly held. The burgh possesses a neat town-house, containing a jail with apartments for courts. Besides the established church, which is an elegant modern building, there is an United Associate Synod meeting-house. There is a public grammar-school, with other private seminaries of education. No manufactures are carried on in the town, but in the neighbourhood there is an extensive distillery, a magnesia work, and some salt-pans. The chief trade of the place consists in the shipment of coal, of which article large quantities are here embarked. Railways have been laid between the coal-pits and the harbour. The port of Inverkeithing is, by authority, a place where vessels ride quarantine; and here government has stationed a body of officers, with a lazaretto, on shore. In 1821 the population amounted to about 1400, and in 1831 to 3189.

INVERLOCHY, or Innerlochy, a place in the West Highlands of Scotland, in the county of Inverness. It is situated on the east shore of Loch Eil, near the spot where that arm of the sea is joined by the Caledonian Canal. The town of Fort William lies contiguous to it on the south. According to legendary lore, this place is declared to be the site of a city once the greatest in Scotland, and that here King Achaius signed a treaty with Charlemagne. The remains of the ancient pavement of streets are ostentatiously pointed to as corroborating these fanciful conjectures; but if ever a town existed here, many ages have elapsed since the last vestige of it disappeared, and nothing now remains but a huge quadrangular edifice, styled Inverlochy Castle, which towers in solitary magnificence, and has survived all tradition respecting its origin. The building forms a court, and is provided at the angles with round towers, of the most massive proportions, the whole fabric covering a space of 1600 yards. Inverlochy gives its name to one of the most brilliant victories of the Marquis of Montrose, which he gained in February 1645.

INVERNESS, the only large town in the county, and usually styled the capital of the Highlands, is finely situated on the banks of the river Ness, where it falls into the Moray Frith. The ancient and principal part of the town is on the east side of the river; but, since the construction of the Caledonian Canal, houses and streets are extending towards the west. Some writers have invested Inverness with a fabulous antiquity. It is certain that it was one of the Pictish capitals, was early incorporated as a free town, and received four charters from William the Lion. In 1412, Inverness was burned by Donald, Lord of the Isles, on his march to the battle of Harlaw. A castle stood to the east of the town, in which Macbeth is said to have murdered King Duncan. This fortress was razed to the ground by Malcolm Ceanmore, and another built on an eminence by the river side, which continued as a royal fortress till blown up by the troops of the Pretender in 1746. This hill is now the site of a beautiful castellated structure, containing the court-house, county-rooms, and record office, built in 1835. In the centre of the burgh is the town-hall, erected in 1708, in front of which is placed the ancient cross of the burgh, and a large circular stone, or collection of stones, bound round with iron hoops, called *Clach-na-cuden*, or Stone of the Tubs, on which the servants used to rest their pails in carrying water from the river. At the northern extremity of the town are the remains of a fort built by Oliver Cromwell, capable of accommodating 1000 men. The site of this erection, part of the ramparts of which still remain, has been converted into a manufactory for thread and sacks. There are two bridges over the river Ness, one a handsome stone bridge of seven arches, built by public subscription in 1685, and the other a strong wooden bridge, erected about twenty years ago. In 1826, gas was introduced for lighting the town; and in 1830, the supplying it with water, conveyed in pipes from the river, was carried into effect. In 1831 the streets of

Inverness-shire.

Inverness were paved anew with granite, and common sewers made, the whole costing about L.6000. The jail, which is small and inconvenient, was built in 1791, at an expense of L.1800, and is ornamented with a fine spire, which cost L.1600 more. There are two churches belonging to the establishment, one for English and the other for Gaelic, which is still spoken by the lower class of the inhabitants, especially in the country. It is in contemplation to erect a new church, for which large subscriptions have been received. A handsome Catholic chapel was erected in 1835. There is a neat Episcopalian chapel, and places of worship for the Seceders, the Independents, and Methodists. Inverness has also a royal academy, at which about 250 pupils attend. Races were formerly held here, but they have been discontinued for several years. There are assembly rooms, elegantly fitted up. There are four banking establishments in Inverness, two weekly newspapers, and two public reading-rooms. No town has improved so rapidly in the arts and embellishments of social life; but its admirable situation for trade has not been sufficiently improved. The steam-boats between Inverness and Glasgow have increased the traffic in this direction; and were a woollen manufactory, or other undertaking of a similar nature, established, the Caledonian Canal and the Moray Frith, affording an unlimited command of water-power in every direction, might be turned to great advantage. The population of the town and parish in 1831 amounted to 14,324, that of the town alone being 9663. Of the present population, 529 families are chiefly engaged in agriculture, 1015 families employed in trade, and 1766 not included in either of these classes.

INVERNESS-SHIRE, the most extensive county in Scotland, situated between 56° 40′ and 57° 36′ north latitude, and between 3° 50′ and 5° 50′ west longitude from Greenwich, is bounded on the north by the shires of Ross and Cromarty; on the east by those of Aberdeen, Banff, Moray, and Nairn, and by the Moray Frith; on the south by the counties of Perth and Argyle; and on the west by the Atlantic Ocean. It is from fifty to seventy-five miles in length; in breadth from thirty to fifty miles; and its area is computed at 3036 square miles, of which the space occupied by lakes has been estimated at 132 miles, and the land at 2904, or 1,858,560 English acres.

The exterior outline of this county is exceedingly irregular. On the north-east, where the county town is situated, a narrow tract runs out between Nairnshire and the Moray Frith. Farther to the east, a portion of it is detached and enclosed by the counties of Moray and Banff; Argyleshire penetrates into it from the south-west; and on the west it is indented by Lochs Moidart, Aylort, Nevis, Hourn, and other arms of the sea.

The surface is still more varied, consisting of ranges of lofty mountains, alternating with deep narrow valleys, the beds of a great many lakes and rivers. The most prominent feature is Glenmore, or the Great Glen, for the most part a mile in breadth, and bounded on either side by precipitous high grounds, which traverses the county from south-west to north-east, dividing it into two nearly equal parts. In this glen, from north to south, are Loch Ness, Loch Oich, and Loch Lochy, which, being united by the Caledonian Canal, form a line of inland navigation between the east and west seas, or from the Moray Frith on the north-east, to Linnhe Loch, an arm of the Atlantic, on the south-west, a distance of about sixty miles, for frigates of thirty-two guns, and vessels of 600 tons. Loch Ness is remarkable for never freezing, a circumstance ascribed to its great depth; and for its waters having been violently agitated during the great earthquake at Lisbon in November 1755. On each side of this valley there is a number of glens and straths, separated by mountainous ridges, with lakes which receive the waters from the high grounds, and discharge them by outlets, partly into the lakes in the central valley, and partly, by a more direct course, into the arms of the Atlantic on the west, or by rivers which flow from this county into the counties on the east, and thence into the German Ocean.

The western side, or the country between the great valley and the Atlantic, from Argyleshire on the south to Ross-shire on the north, a distance of about seventy miles, is the most wild and mountainous tract of Inverness-shire, and is therefore known by the name of the *Rough Bounds;* yet, before reaching the sea-coast, the general elevation is somewhat diminished. In this tract, beginning at the south, the principal divisions are, Moidart, Arasaig, Morar, Knoidart, and Glenelg, which contain a variety of glens or valleys, among which are, Glengarry, Glen Moriston, Glen Urquhart, and Strathglass. The most considerable lakes in this quarter are, Loch Eil, Loch Shiel, Loch Arkaig, Loch Garry, and Loch Maddy. Lochan Uain, in the parish of Kilmorack, about forty miles west from Beauly, is said to have been known to remain frozen all the year through. On the east side of the valley lies the extensive district of Badenoch; at its southern termination is Lochaber; and at its northern the Aird, the most fertile part of the county. These divisions also include a great many glens, lakes, and rivers, extensive woodlands, and not a little productive land. The principal valleys here are Glenroy, noted for its parallel roads, which, it is now agreed, must have been formed by the gradual subsidence of the waters, and not by the hand of man; Strathspey, Stratherrick, Strathearn, and Strathnairn. Treig, Ericht partly in Perthshire, Laggan, Insch, and Moy, are the names of the most considerable of the lochs in this quarter; and here the Spey, the Findhorn, and the Nairn, and a number of smaller streams, have their source.

The general aspect of Inverness-shire may be further conceived, when it is stated that two thirds of the surface are covered with heath; that only a fortieth part is corn land; and that the corn land, woodlands, and green pastures, together, do not exceed eight acres in an hundred. In many large tracts heath prevails to such a degree that, for twelve or fourteen miles, scarcely any verdure is to be seen, except where a solitary rivulet has occasionally overflowed its banks. On the south of Badenoch there is a flat of deep moss, supposed to be the most extensive in Britain, in which a great number of small lakes are interspersed, some of them containing wooded isles, where the deer, from the inaccessible nature of the ground, find shelter from their pursuers. But the far greater part of the county is occupied with mountains. Ben Nevis, 4380 feet high, stands on the south-west, a little to the east of the Caledonian Canal; Meal Fourvounie, on the west of Loch Ness, is more than 3000 feet high; and Cairngorm, partly in Banffshire, upwards of 4000. It has been remarked, as a singular circumstance, that several of the hills, which are covered with heath on the sides, are green on the summit, and produce valuable pasturage. The productive land lies chiefly on the sea-coast, and along the banks of the lakes and rivers; much of it in the latter situation is alluvial and fertile. There is also clay in a few places; but the prevailing soil is sand, or a sandy loam, well adapted to the growth of barley, potatoes, turnips, and other green crops.

The principal rivers of Inverness-shire are, the Spey, which rises from a loch of that name, a little to the east of the Great Valley, and, flowing in a course from south-west to north-east for about ninety-six miles, falls into the sea about eight miles east of Elgin, in Morayshire, carrying with it the waters of 1300 square miles; the Ness, which issues from Loch Ness, and, flowing through the town of Inverness, falls into the Moray Frith, after a course of six miles; the Lochy issues from Loch Lochy, and has a course of ten miles westward, till it falls into Loch Eil near Fort William; soon after it leaves its parent lake, it is joined, from the east, by the Spean, which is remarkable for being crossed by a bridge, two of the arches of which are ninety-five feet high; and the Beauly, which has its source in the north-west, and carries the united waters of the Glass and other two rivulets into the frith of the same name. The Findhorn and Nairn on the east, and the Garry and the Morriston on the west, are smaller streams. The Foyers, which flows into Loch Ness from the south, is remarkable for its celebrated falls, one of which, according to Dr Garnet, is seventy feet, and the other, half a mile lower, 212 feet. There are cascades not inferior to these in the parish of Kilmorack, on the waters which unite to form the Beauly, and at Loch Leven head in the southern quarter; near which last place there are also some remarkable caverns.

Granite, limestone, slate, marble, brick-clay, abound in many parts of Inverness-shire. Lead has been discovered in Ben Nevis, and at three other places in that neighbourhood, and also at Glengarry, but none of it is wrought. A vein of plumbago has also been found at Glengarry. A great part of the mountain of Ben Nevis is composed of beautiful porphyry. There is no coal, and for want of it much of the limestone is of little value.

From the trees found in great numbers, and some of them of a remarkable size, in all the mosses, there is reason to believe that this country was, at an early period, almost covered with wood; and at present there is a greater space covered with natural pines here than in all the rest of Britain. In Strathspey it is said that three tiers of stocks have been found, directly above one another, in a moss; from which it is inferred that the deepest must have come to maturity, and been destroyed, before the one next above it was formed. In the same district there are about 15,000 acres of natural firs, besides 7000 of planted firs and larches; and the natural woods on Loch Arkaig, in Glengarry, Glenmoriston, Strathglass, Strathfarrer, and at the head of Loch Shiel, are also very extensive. Full-grown trees of ash, lime, beech, oak, plane, and mountain-ash, are found at Castle Grant, Culloden, and Belladrum, in the northern quarter of the county; but in most other places the woods are in the state of coppice. The birch is in great abundance on the sides of Loch Ness, Loch Laggan, about Rothiemurchus, and in the vale of Urquhart. Part of the great Caledonian Forest extends for several miles near the boundary of this county with Perthshire. Considerable tracts have been planted, chiefly with firs and larches, particularly in the north-east, where the county town is situated, in Badenoch, and on Loch Eil.

There are several fishing villages on the east coast, yet the sea-fishery is not prosecuted to a great extent. But the arms of the sea, and the numerous lakes and rivers, afford an abundant supply of fish. The herring occasionally visits Loch Eil; salmon yield a considerable rent on the rivers Lochy, Beauly, and Ness, and are found also in the Morrer, in Loch Insch in Badenoch, and at Invermoriston. Char is caught in several of the lochs, and flounders and sprats in the Beauly. The moors and woodlands are plentifully stocked with game, viz. red and roe deer, the Alpine and common hare, black game and ptarmigan, grouse, partridges, &c.; and pheasants have lately been introduced. Foxes and wild cats are still numerous, and, in the lakes and rivers, otters. There are also eagles, hawks, and owls; and a multitude of water fowls, particularly swans, resort to Loch Insch, and the other lakes of Badenoch.

The territory of Inverness-shire is divided into estates of great extent, and, in proportion to the rental of the county, of great value. In 1804 more than the half, if we may judge from the old valuation, belonged to seven proprietors, and as much more was held by other six, as made the possessions of these thirteen individuals equal to more than two thirds of the whole; each of them, at a medium, must, therefore, have contained about 100,000 acres. There are thirty-nine estates valued at above L.500, and thirty-five estates below L.500 and above L.100. The greatest landed proprietors are Lord Macdonald, the Earl of Seafield, Mr Fraser of Lovat, Mackintosh of Mackintosh, Macleod of Macleod, Macdonell of Glengarry, Colonel Cameron of Lochiel, Lord Glenelg, the Earl of Moray, Chisholm of Chisholm, Colonel Macniel of Barra, Lord Dunmore, Mr Grant of Ballindalloch, Mr Stewart of Belladrum, Mr Baillie of Lochaber, Mr Grant of Glenmoriston, &c. The valuation taken in 1601 was L.73,188. 9s. Scots, and in 1811 the real rent of the lands was L.195,843. 15s. sterling, and of the houses, L.9235. 2s. sterling. The valuation taken in 1814 was L.152,078. 12s. 2½d.; but this sum is nothing like the real rent, being made merely for collecting the property tax. There are several estates of very considerable income, though not of great extent, such as Muirtown, Insches, Culduthell, and others. The old valuation of the whole of Scotland, as fixed about the middle of last century, and which is still the rule by which county assessments are imposed, is to the actual rent of the lands alone in 1811, as L.1 Scots is to L.1.263 sterling; whereas in this county, rents have risen in so much greater a proportion than in the rest of Scotland, chiefly perhaps owing to the introduction of sheep-farming, that its valuation is to its actual rent only as L.1 Scots is to L.2.675 sterling; and it is worthy of remark, that this rise cannot be ascribed in any considerable degree to the outlay of capital by proprietors, in building or otherwise, as in most other parts of Scotland.

Of the occupiers of the land, tacksmen, small tenants, and cottars, of the size of the farms, and the rural economy of the county generally, we have little to say in addition to what we have already offered under the Highland counties of Scotland in the preceding part of this work. Small spots of corn-land contiguous to the hamlets, of which the alternate ridges or lands belong to different cultivators, who used to interchange their allotments once a year, and more recently only once in three years; a larger space of *outfield* beyond this, part of which is constantly cropped till it is exhausted, and then left to nature, when another part, which had been treated in the same manner, but which has been somewhat restored in the mean while by the folding of cattle, takes its place; and beyond this outfield, separated from the higher grounds by a *head dike*, large tracts of common pasture; these, with their miserable huts, their irregular and always inefficient labour, their indolence, and their poverty, present a striking picture of what must have been the condition of the great body of the people of Scotland during the feudal ages; but it is not now, as it was then, somewhat relieved by hospitality and protection on the one side, and respect, gratitude, and attachment, on the other.

This system, indeed, has been gradually approaching to its termination during the last thirty years, and in some parts of Inverness-shire it exists no longer in its original form. The change has been chiefly effected by the introduction of sheep, which has occasioned many complaints, and probably much real suffering for a time to many individuals, but which is likely in the end to be most advantageous to the public at large. With respect to its effect on population, one main topic of declamation, it has not been such as its opponents allege; for the population of Inverness-shire, any more than of the Highlands in general, has not diminished. On the contrary, its increase in this county, from 1755 to 1811, has been much greater than in

Inverness-shire.

Haddingtonshire and the other merely agricultural districts of Scotland. Within that period, it has increased from 64,656 to 78,336, or upwards of twenty-one per cent., whilst that of all Scotland has not been more than forty-four per cent.; and it is well known that the far greater part of this apparently general increase has been occasioned by the extension of manufactures and commerce, and is chiefly confined to a few districts.

The principal exports are cattle, sheep, wool, timber, and slates. The corn grown in the county, chiefly bear or big, and oats, and only on the east coast wheat, is all consumed within itself, much of the bear in illicit distillation; as well as all the potatoes, the most important article of food for the greater part of the year; and the products of the dairy. It imports coals, lime, flour, oatmeal, groceries, and other articles of domestic consumption. The manufactures are, bagging from hemp, thread, kelp to a considerable extent on the west coast, with some tiles and bricks. There are also tan-works, breweries, bleachfields, and an iron-foundery; and some attempts have been made at different periods to carry on branches of the woollen manufacture.

From the west sea a few vessels come up to Fort William, from which the exports are wool, skins, herrings, kelp, and slates. The most considerable village is Maryburgh, or Gordonsburgh, near Fort William. Grantown is a neatly built village on the great road along the Spey, and, under the auspices of Sir James Grant, the proprietor, it has made considerable progress. It contains a town-house and prison, with a well-endowed school; and a few years ago a factory was begun for carding and spinning wool, and for making blankets and woollen cloths. Fairs are held for the sale of cattle, sheep, and wool, at Fort William, Beauly, Grantown, and Kingussie, and four in the year in Inverness, where there is also a well-supplied market every Tuesday and Friday. Some years back an easy communication was formed throughout the greater part of the county, by means of the roads made under the direction of theParliamentary Commissioners for Highland Roads and Bridges, half the expense of which is borne by the county, and the other half is granted by parliament.

Amongst the antiquities of Inverness-shire, which we can only notice generally, are the circles of stones ascribed to the Druids, which are found in many parts of the county, particularly at Corrimony in its northern quarter; two artificial mounts in the parish of Petty, supposed to have been places for administering justice; round buildings, called Picts' Houses, in Glenelg, and other parts; forts, built without mortar, one of which, called Castle Spynie, two miles east from the church of Beauly, encloses a circle of fifty-four yards, and another, in the parish of Laggan, stands on a rock, a hundred yards in perpendicular height; vitrified forts on the hill of Craig Phadric, about two miles from Inverness, Dundhairdghall in Glen Nevis, and Dun Thion near the river Beauly; and a variety of castles, of which Inverlochy Castle, a building of great extent and unknown antiquity, on the banks of the Lochy, near Fort William, is, perhaps, the most remarkable. On a hill near Inverness, called the Castle Hill, stood the castle of the Thane of Cawdor, where Macbeth is said to have murdered Duncan. It was razed by Malcolm Ceanmore, who removed the town to the northward, where it now stands, granted its first charter, and built a fortress on the site of the old town, which was repaired in 1715, and finally demolished in 1765. Cromwell erected a citadel at the mouth of the river Ness, which was demolished by Charles II.

There is a chain of forts stretching across the island, along the line of the Caledonian Canal. Fort George is a regular fortress, mounting eighty guns, with barracks for 3000 men; it was begun in 1747, and completed in twenty years, at an expense of about L.160,000. It is situated eleven miles eastward from Inverness, upon a neck of land on the Moray Frith, opposite to Fortrose in Ross-shire. Fort Augustus, also a regular fortification, though a place of no great strength, with four bastions, and barracks for 400 men, is situated at the west end of Loch Ness, nearly midway between the east and west seas. It was first built in 1730, at some distance from Loch Ness; but having been demolished by the rebels in 1745, it was afterwards rebuilt nearer the lake. Fort William, built in the reign of William III., is situated on a navigable arm of the sea, called Loch Eil, at the south-western termination of the great valley. These forts are now useless in a military point of view, though kept in a state of good repair, and answering as barracks for a few soldiers. On Culloden Moor, a level heath to the eastward of Inverness, on the 16th April 1746, was fought the battle which put an end to the rebellion of 1745; the greater part of this heath is now covered with plantations.

Inverness-shire contains twenty-eight entire parishes, and shares several others with the counties of Argyle, Nairn, and Moray. Of these, twenty are on the mainland, and the remainder in its islands. Some of the parishes on the mainland, as well as in the islands, would form a square of twenty miles each. Kilmalie and Kilmorack are still larger, extending in length about sixty miles, and in breadth almost thirty. Many of the inhabitants are Roman Catholics, particularly in the districts of Moidart, Arasaig, Morar, and Knoidart, on the west side. The county sends one member to parliament, and the town of Inverness, along with Forres, Nairn, and Fortrose, choose one for the burghs. The sheriff holds courts at four places, two of which, Inverness and Fort William, are for the mainland, and two more for the isles in Skye and Long Island. The population of the whole shire in 1811, 1821, and 1831, is given in the annexed table. (See the *Statistical Account of Scotland;* Playfair's *Description of Scotland;* Robertson's *Survey of Inverness-shire; The Beauties of Scotland*, vol. v.; and the *General Report of Scotland.*)

YEAR.	HOUSES.			OCCUPATIONS.			PERSONS.

INVERSE, the opposite of direct, is applied to a particular form of proportion. See ARITHMETIC.

INVERSION, the act by which any thing is inverted or turned backwards. Problems in geometry and arithmetic are often proved by inversion; that is, by a contrary rule or operation.

INVERSION, in *Grammar*, is where the words of a phrase are ranged in a manner not so natural as they might be. For instance, "Of all vices, the most abominable, and that which least becomes a man, is impurity." Here is an inversion, the natural order being, "Impurity is the most abominable of all vices, and that which least becomes a man." An inversion is not always disagreeable, but sometimes has a good effect.

INVERTED, in *Music*, signifies a change in the order of the notes which form a chord, or in the parts that compose harmony, which happens by substituting in the bass, those sounds which ought to have been in the upper part; an operation not only rendered practicable, but greatly facilitated, by the resemblance which one note has to another in different octaves. Hence we derive the power of exchanging one octave for another, or substituting in the extremes those which ought to have occupied the middle station, and *vice versa*.

INVERURY, a royal burgh of Scotland, in the county of Aberdeen, and capital of a parish of the same name. It is pleasantly situated in the angle of land near the confluence of the Urie and Don, at the distance of sixteen miles north-west of Aberdeen. The oldest charter is a *novodamus* by Queen Mary, narrating that Inverury had been a royal burgh from time immemorial, but that the charter had been lost during the civil wars. Tradition relates that it was granted by Robert Bruce, after he had gained a battle over the English at this place, the first of that series of victories by which that monarch achieved the independence of his country. The town is small, and its trade is only in manufactures for local use. Besides the parish church, there are two dissenting meeting-houses. The population of the burgh and parish amounted in 1821 to 1129, and in 1831 to 1419.

INVESTIGATION properly denotes the searching or finding out any thing by the tracts or prints of the feet; and hence mathematicians, schoolmen, and grammarians, have employed the term in their respective researches.

INVESTITURE, in *Law*, a giving livery of seisin or possession. There was anciently a great variety of ceremonies used upon investitures, which at first were made by a certain form of words, and afterwards by such things as had the greatest resemblance to the thing to be transferred. Thus, where lands were intended to pass, a turf was delivered by the granter to the grantee. In the church, it was customary for princes to make investiture of ecclesiastical benefices, by delivering to the person they had chosen a pastoral staff and a ring.

INVOCATION, in *Theology*, the act of adoring God, and especially of addressing him in prayer for his assistance and protection.

The difference between the invocation of God and of the saints, as practised by the Roman Catholics, is thus explained in the catechism of the council of Trent. "We beg of God," says the catechism, "to give us good things, and to deliver us from evil; but we pray to the saints to intercede with God and obtain those things which we stand in need of. Hence we use different forms in praying to God and to the saints; to the former we say, *hear us, have mercy on us;* to the latter we only say, *pray for us.*" The council of Trent expressly teaches that the saints who reign with Jesus Christ offer up their prayers to God for men, and condemns those who maintain the contrary doctrine. The Protestants reject and censure this practice as contrary to Scripture, deny the truth of the fact, and think it highly unreasonable to suppose that a limited finite being should be in a manner omnipresent, and at one and the same time hear and attend to the prayers which are offered to him in England, China, and Peru; and hence they infer, that if the saints cannot hear their requests, it is inconsistent with common sense to address any kind of prayer to them.

INVOCATION, in *Poetry*, an address at the beginning of a poem, in which the poet calls for the assistance of some divinity, particularly of his muse, or the deity of poetry.

INVOICE, an account, in writing, of the particulars of merchandise, with the value, customs, charges, &c. thereof, transmitted by one merchant to another in a distant country.

INVOLUCRUM, amongst botanists, expresses that sort of cup which surrounds a number of flowers, every one of which has, besides this general cup, its own particular perianthium. The *involucrum* consists of a multitude of little leaves disposed in a radiated manner.

INVOLUTION, in *Algebra*, the raising any quantity from its root to any height or power assigned. See ALGEBRA.

IO, in fabulous history, daughter of Inachus, or, according to others, of Jasus or Pirene, was priestess of Juno at Argos. Jupiter became enamoured of her; but Juno, jealous of his intrigues, discovered the object of his affection, and surprised him in the company of Io. Jupiter changed his mistress into a beautiful heifer; and the goddess, who well knew the fraud, obtained from her husband the animal whose beauty she had condescended to commend. Juno commanded the hundred-eyed Argus to watch the heifer; but Jupiter, anxious for the situation of Io, sent Mercury to destroy Argus, and to restore her to liberty. Io, freed from the vigilance of Argus, was now persecuted by Juno, who sent one of the Furies to torment her. She wandered over the greater part of the earth, and crossed the sea, till at last she stopped on the banks of the Nile, still exposed to the unceasing torments of the Fury. Here she entreated Jupiter to restore her to her natural form; and when the god had changed her from a heifer into a woman, she brought forth Epaphus. Afterwards she married Telegonus, king of Egypt, or Osiris according to others; and she treated her subjects with such mildness and humanity, that after death she received divine honours, and was worshipped under the name of Isis. According to Herodotus, Io was carried away by Phœnician merchants, who wished to make reprisals for Europa, who had been stolen from them by the Greeks.

IOLAIA, a festival at Thebes, the same as that called *Heracleia*. It was instituted in honour of Hercules and his friend Iolas, who assisted him in conquering the hydra. It continued during several days, on the first of which were offered solemn sacrifices; the next day horse-races and athletic exercises were exhibited; the following day was set apart for wrestling; and the victors were crowned with garlands of myrtle generally used at funeral solemnities. But they were sometimes rewarded with tripods of brass. The place where the exercises were exhibited was called *Iolaion*, where were to be seen the monument of Amphitryon and the cenotaph of Iolas, who was buried in Sardinia. These monuments were covered with garlands and flowers on the day of the festival.

IOLAS, or IOLAUS, in *Fabulous History*, a son of Iphiclus, king of Thessaly, who assisted Hercules in conquering the hydra, and burned with a hot iron the place where the heads had been cut off, to prevent the growth of others. He was restored to youth and vigour by Hebe, at the request of his friend Hercules. Some time afterwards Iolas assisted the Heracleidæ against Eurystheus, and killed the tyrant with his own hand. According to Plutarch, Iolas had a monument in Bœotia and Phocis, where lovers used to go and bind themselves by the most solemn oaths of fidelity, considering the place as sacred to love and friendship. According to Diodorus and Pausanias, Iolas died and was buried in Sardinia, where he had gone to make a settlement at the head of the sons of Hercules by the fifty daughters of Thespius.

ION, in fabulous history, a son of Xuthus, and Creüsa, daughter of Erechtheus, who married Helice, the daughter of Selinus king of Ægiale. He succeeded to the throne of his father-in-law, and built a city, which he called *Helice*, on account of his wife. His subjects received from him the name of *Ionians*, and the country that of *Ionia*. See Ionia.

Ion, a tragic poet of Chios, who flourished about the eighty-second Olympiad. His tragedies were represented at Athens, where they met with universal applause. He is mentioned and greatly commended by Aristophanes, Athenæus, and others.

IONA, or Icolmkill, one of the Hebrides, a small but celebrated island, "once," as Dr Johnson expresses it, "the luminary of the Caledonian regions, whence savage clans and roving barbarians derived the benefits of knowledge and the blessings of religion." The name *Iona* is derived from the Hebrew word signifying a *dove*, in allusion to Columba, who landed here in 565. It is said to have been a seat of the Druids before his arrival, when its name in Irish was *Inis Drunish*, or the Druid Island. The Druids being expelled or converted, Columba founded here a cell of canons regular, who, till 716, differed from the church of Rome in the observance of Easter and in the tonsure. After his death the island retained his name, and was called *Ycolumb cill* or Columb's cell, now *Icolmkill*. The Danes dislodged the monks in the seventh century, and the Cluniacs were the next order who settled here.

This island, which belongs to the parish of Ross, in Mull, is three miles long and one broad. The east side is mostly flat, the middle rises into small hills, the west side is very rude and rocky, and the whole forms a singular mixture of rock and fertility. There is in the whole island only one village, or rather collection of huts, inhabited by a population of about 450 individuals, for whose education and religious improvement a church and schoolhouse have been erected by the Society for the Diffusion of Christian Knowledge. Near the town is the bay of the martyrs who were put to death by the Danes. An oblong enclosure, bounded by a stone dyke, and called *Clach-nan-Druinach*, in which bones have been found, is supposed to have been a burial-place of the Druids, or rather the common cemetery of the town's people. Beyond the town are the ruins of the nunnery of Austin canonesses, dedicated to St Oran, and said to have been founded by Columba. The church was fifty-eight feet by twenty, and the eastern roof is entire. On the floor, covered deep with cow-dung, is the tomb of the last prioress, with her figure praying to the Virgin Mary, and this inscription on the ledge: *Hic jacet domina Anna Donaldi Ferleti filia, quondam prioressa de Jona, quæ obiit an'o m° d° xi^mo ejus animam Altissimo commendamus*; and another inscribed, *Hic Jacet Mariota filia Johan. Lauchlain domini de....* A broad paved way leads hence to the cathedral; and on this way there is a large handsome cross called Macleane's, the only one that remains of three hundred and sixty which were demolished here at the Reformation. Reilig Ouran, or the burying-place of Oran, is the large enclosure where the kings of Scotland, Ireland, and of the isles, with their descendants, were buried, in three several chapels. The dean of the isles, who travelled in 1549, and whose account has been copied by Buchanan, says, that in his time, on one of these chapels, or "tombes of stain formit like little chapels, with ane braid gray marble or quhin stain on the gavil of ilk ane of the tombes," containing, as the chronicle says, the remains of forty-eight Scotch monarchs, from Fergus II. to Macbeth, sixteen of whom were pretended to be of the race of Alpin, was inscribed *Tumulus regum Scotiæ*; the next was inscribed *Tumulus regum Hiberniæ*, and contained four Irish monarchs; and the third, inscribed *Tumulus regum Norwegiæ*, contained eight Norwegian princes, or viceroys of the Hebrides, whilst these islands were subject to the crown of Norway. Boecius says, that Fergus founded this abbey to serve as a burial-place for his successors, and caused an office to be composed for the funeral ceremony. All that Mr Pennant discovered here, consisted in certain slight remains, built in a rigid form, and arched within, but the inscriptions were lost. These were called *Jornaire nan righ*, or "the ridge of the kings." Amongst those stones are to be seen only two inscriptions, in the Gaelic or Erse language, but written in the ancient Irish characters: *Cros Domhail fat'asich*, "the cross of Donald Longshanks," and that of *Urchvine o Guin*; and another inscribed *Hic jacet priores de Hy, Johannes, Hugenius, Patricius, in decretis olim baccalaureus, qui obiit an. Dom. milles^mo quingentesimo.* About three hundred inscriptions were collected here by Mr Sacheverel in 1688, and given to the Earl of Argyll, but afterwards lost in the troubles of the family. The place is in a manner filled with grave-stones, but so overgrown with weeds that few or none are at present to be seen, far less can any inscriptions be read. Here also stands the chapel of St Oran, the first building commenced by Columba, which the evil spirits would not suffer to stand till some human victim had been buried alive; a service for which Oran offered himself, and his red grave-stone is still to be seen near the door. In this chapel are tombs of several chiefs, and others. A little north-west of the door is the pedestal of a cross, on which are certain stones that seem to have been the supporters of a tomb. Numbers who visit this island think it incumbent on them to turn each of these thrice round, according to the course of the sun. They are denominated *Clachabrath*; for it is thought that the *brath*, or end of the world, will not arrive till the pedestal on which they stand is worn through. Mr Sacheverel informs us, that originally there were here three noble globes of white marble, placed on three stone basons, and that these were turned round; but the synod ordered them and sixty crosses to be thrown into the sea. The present stones are probably substituted instead of these globes. The precinct of these tombs was held sacred, and enjoyed the privileges of a girth or sanctuary. These places of retreat were, by the ancient Scotch law, not designed to shelter indiscriminately every offender, as was the case in more bigoted times in Catholic countries; for here all atrocious criminals were excluded, and none but the unfortunate delinquent or the penitent sinner was shielded from the instant stroke of rigorous justice. A little to the northward of this enclosure stands the cathedral, built in the form of a cross, 115 feet long by twenty-three broad, and the transept seventy feet; the pillars of the choir have their capitals charged with scriptural and other histories; and near to the altar are the tombs of two abbots and a knight. A fragment remains of the altar stone, of white marble veined with gray. This church is ascribed to Maldwin, in the seventh century; but the present structure is far too magnificent for that age. Most of the walls are built of red granite, from the Nun's Island in the Sound. Two parallel walls of a covered way, about twelve feet high and ten wide, reach from the south-east corner to the sea. In the church-yard is a fine cross of a single piece of red granite, fourteen feet high, twenty-two inches broad, and ten inches thick. Near to the south-east end is Mary's chapel. The monastery is behind the chapel, of which only a piece of the cloister remains, and some sacred black stones in a corner, on which contracts and alliances were made and oaths sworn. To the east of it were the abbot's gardens and offices; and to the north was the palace of the bishop of the isles after the separation from them of Man. This see was endowed with thirteen islands, several of which were frequently taken away by the chieftains. The title of *Soder*, which some explained as Σωτηρ, *Soter*, the name of Christ, or Soder an imaginary town, is really derived from the distinction of the diocese into the northern islands or Nordereys, that is, all to the north of Ardnamurchan Point, and the Southern or Sudereys; which last being the most important, the Isle of Man retained both titles.

Other ruins of monastic buildings and offices may be traced, as well as some druidical sepulchral remains. Several abbeys were derived from this, which, with the island, was governed by an abbot-presbyter, who had rule even over bishops. The place where St Columba landed is a pebbly beach, where a heap of earth represents the form of his ship. Near it is a hill with a circle of stones called *Cnoc-nan aimgeal*, or "the hill of angels," with whom the saint held conference; and on Michaelmas day the inhabitants coursed their horses round it, a relic of the custom of bringing them there to be blessed. In former times this island was the place where the archives of Scotland and many valuable old manuscripts were kept. Of these most are supposed to have been destroyed at the Reformation; but many, it is said, were carried to the Scotch college at Douay in France, and it is hoped some of them may still be recovered. In 1830 an intelligent antiquary cleared away the rubbish from the ruins of the religious edifices, for the purpose of bringing to light every relic that might remain. In this search, besides the advantages resulting from disentombing these interesting ruins, and exposing them to the eye of the visitor, a great many statues and monuments were discovered.

IONIA, a district of Asia Minor, extending along the coasts of the Ægean Sea about 3430 stadia ($428\frac{3}{4}$ miles), according to Strabo, if we include the sinuosities of the coast, though by land the distance was much shorter. To the north its boundary was the cape near which stood the city Phocæa, close to the river Hermus; and to the south the promontory Posidium, in the Milesian territory, on the left bank of the Mæander. It was separated in the interior from the plain of Lydia by a chain of mountains extending from the river Hermus, now *Sarabat*, to the Caÿster, a ridge which was known to the ancients by the celebrated names of Tmolus and Sipylus. A continuation of this ridge, under the name of Messogis, ranged along the rest of the Ionian coast, till it terminated in the promontory of Mycale. The fertility of this small district was only equalled by the excellence of its climate, and every creek furnished excellent harbours for shipping. Its inhabitants rivalled Greece in all the arts and sciences, and in elegance and purity of taste excelled even the mother country. The Ionian temples were remarkable for their grandeur of design and beauty of proportions, and the schools of painting and sculpture were the admiration of the world. Ionia was watered by the river Hermus, now *Sarabat*, whose waters were said to bring down golden sands; the Cayster, now the *Little Mendere;* and the Mæander, now the *Great Mendere.*

We find the Ionians first occupying Attica and that part of the Peloponnesus called Ægialos, but afterwards better known as Achaia. From this district they were driven out by the Achæi, and took refuge in Attica, where they found a dispute respecting the succession to the throne of Athens, between Medon and Neleus, the descendants of Codrus. When the oracle of Delphi decided in favour of the former, Neleus determined to abandon this country and seek a settlement elsewhere. He invited the Ionians to join him, and having set sail with a large body of Greeks collected from every part of the country, he, along with several of his brothers, proceeded to the coast of Asia, where they founded cities on that part of the coast which was from them called Ionia. The cities were twelve in number, and, not long after their foundation, united themselves into one political body, called the Ionian confederacy. Their names were Miletus, Myus, and Priene, in the district of Caria; Ephesus, Colophon, Lebedus, Teos, Erythræ, Clazomenæ, and Phocæa in Lydia; Samos and Chios on the islands adjacent to Lydia. Smyrna was in later times admitted to the privileges of this confederacy. They held their solemn meetings and festivals in a temple called Panionium, dedicated to the Heliconian Neptune, and erected on the promontory of Mycale, opposite to Samos. The government of each state seems to have been monarchical, but they do not appear to have made any vigorous efforts to maintain their independence. We find them first subject to the effeminate Lydians, and afterwards to the more powerful but equally mild sway of the Persians. There were, indeed, some instances of patriotic resistance; but as a nation they showed themselves weak and contemptible. They indeed made one bold effort to throw off the Persian yoke, about 500 B. C., led on by Aristagoras and Histiæus; but they proved unequal to the task. Though they showed much zeal and ardour in the commencement of the undertaking, they had not perseverance sufficient to insure success in a protracted contest with the power of Persia. The taking and burning of Sardis served only to exasperate the Persians, and they found themselves soon afterwards obliged to give up all resistance by land. (Herodot. v. 98–123.) The contest was still carried on by sea; but here also they were unsuccessful, and they found themselves compelled to acknowledge the superior power of the Persian monarch. (vi. 7–23.) The victories of the Greeks over Darius and Xerxes, B. C. 490 and 480, enabled Ionia for a short time to regain her freedom; but the battle of Mycale transferred her once more to a foreign power. She now became subject to the Athenians, and during the Peloponnesian war, B. C. 431–405, we find them drawing considerable resources from the tribute imposed on the Ionians. When the Athenians were defeated in Sicily, B. C. 413, they made great efforts to preserve Ionia from the united attacks of Sparta and the Persian satrap Tissaphernes. It does not appear that the Ionians themselves felt much interested in the result of the contest, as no city except Miletus took part in the dispute. But the peace of Antalcidas, B. C. 387, replaced the Ionians in their wonted condition of slaves to the Persian monarch; and neither the passage of Alexander through their country, B. C. 333, nor the subsequent disputes of his captains, seem to have made any material change in their condition. From the weak government of Antiochus they passed under the sway of the Romans, and then became merged in the mighty empire of the latter. From this time they can no longer be considered as a distinct people.

IONIAN ISLANDS.

Ionian Islands.

The Ionian Islands formerly constituted a small part of the Venetian dominions; and, by a fate somewhat singular, they were raised to the rank of an independent power without any efforts of their own, at the very period which witnessed the extinction of Venice itself, with Genoa, Ragusa, and many other small states which had existed for ages. These islands, which are seven in number, exclusively of some small dependent islets, are situated on the western and southern shores of Greece, between 36° and 40° of north latitude, and between 19° 40′ and 23° 10′ of east longitude. Four of them lie in a group opposite the entrance of the Gulf of Corinth; two others, Corfu and Paxo, are situated about eighty miles north-west of this central group, from which Cerigo, the remaining island, is distant about 150 miles south-east. The subjoined table gives a view of their extent and population; but the measurements can only be considered as approximations, as, we believe, no accurate map of all the islands has ever been published.

Modern Names.	Ancient Names.	English Square Miles.	Population.	Authorities.
Cephalonia[1]....	Cephalenia.........	500	60,000	Holland, 1812.
Corfu..........	Corcyra, Phæacia..	270	60,000	Vaudoncourt, 1807.
Zante..........	Zacynthus..........	180	33,352	Williams, 1815.
Santa Maura...	Leucadia...........	150	18,000	Holland, 1812.
Cerigo.........	Cythera.............	130	9,000	Do. 1811.
Theaki.........	Ithaca...............	60	9,400	Williams, 1815.
Paxo...........	Paxus................	20	3,968	Do.
		1310	193,720	

According to this table, these islands contain about 150 persons to each square mile, a density of population nearly equal to that of the most populous countries of Europe, and very remarkable, considering how a great proportion of their surface is too rugged to admit of any species of cultivation.

Climate and diseases.

The climate of the Ionian Islands resembles that of the continent of Greece, except that the surrounding seas temper in a greater degree the extremes of heat and cold, and render the atmosphere more humid. Snow often falls during the winter, and lies on the high grounds, but very rarely in the plains. The winter rains sometimes bring with them great quantities of a reddish sand, which the people think has been transported from Africa by the south wind. Sudden and furious squalls are frequent, and the Sirocco, or hot wind, which occurs at certain periods, produces the usual effects, a dull headach, lassitude, and a sense of oppression. The harvest, which is generally in May on the continent, is here in June. Earthquakes are very frequent, though not often very destructive. In Zante, two or three sometimes occur in a month; it is observed that they are preceded by a peculiar state of the atmosphere, producing a feeling of heaviness, or a sulphurous smell, and that they are generally followed by rain. Malaria prevails in low situations in the autumnal months; and the itch, which is common in some parts, instead of being eradicated by medical means, is rather cherished by the people, from a strange notion that it is a preservative against malaria. In other respects the climate is agreeable and healthy, and instances of remarkable longevity are known.[2]

Geology.

The rocks of all these islands belong to the same great calcareous formation which occupies the continent of Greece. They contain some, though very few, organic remains, and are disposed in highly inclined strata. The limestone, which is accompanied occasionally with beds of gray foliated gypsum, and with beds or masses of sandstone, is conjectured by Dr Holland to belong to the first flœtz limestone of Werner. At one spot, ten miles south of the town of Zante, are found a number of pitch wells, agreeing in their situation and appearance with the description given by Herodotus two thousand four hundred years ago. They consist of small pools of water, fed by springs, in a marshy tract near the shore, having their sides and bottoms lined with petroleum in a viscid state, which, by agitation, is raised to the surface in flakes. It is collected once a year, and the produce is about a hundred barrels.[3]

Topography.

The surface of all these islands is so remarkably mountainous, that they do not contain a quantity of arable land nearly sufficient to afford corn to the population; and were it not that the vine, the olive, and the currant, enable them to extract a valuable produce from their rocks and declivities, they could support but a very small number of inhabitants. There is a considerable diversity, however, in the aspect and qualities of the surface of the different islands, which renders it necessary to speak of their topography separately.

Corfu.

To begin with Corfu, the most northern, and the seat of the general government. This island, which is about forty English miles long, and fifteen in extreme breadth, lies opposite the coast of Albania, from which it is separated at one point by a strait two miles broad. A range of mountains occupies the centre of this island, the highest summits of which, Mount Kassopo, must be nearly 4000 feet high, since the coast of Italy, at eighty miles distance, is visible from it. The island is rather bare of wood, and not abundant in good pasturage. Wheat is raised in some low situations near the coast; but though called "fruitful Corcyra" by Dionysius, and celebrated for its riches by other ancient authors, its inhabitants de-

[1] The ancient geographers had a very imperfect idea of the extent of these islands. Strabo (lib. x.) estimates the circumference of Cephalonia at thirty miles (300 stadia), instead of 100; that of Zante at sixteen miles, instead of sixty; and that of Ithaca at eight miles, instead of forty. Pliny (lib. iv.) gives forty-four Roman miles as the circumference of Cephalonia, and thirty-six as that of Zante.

[3] Holland, chap. i. and ii.

pend chiefly on importation for corn, which they procure in exchange for their wine, oil, and salt. The capital, also named Corfu, which lies on the east side of the island, contains about 15,000 inhabitants, and is a pretty strong place. This island is the Phæacia of Homer. A small bay, five or six miles south of the capital, is conceived to be the Alcinus Portus, where Ulysses, after his shipwreck, met with the daughter of Alcinous; and Fano, a small rocky islet seven or eight miles in circumference, lying twelve miles off the north-west coast of Corfu, is the island of Calypso.[1]

Paxo. Paxo, the next in order, which is about seven miles long and three broad, lies eight miles south-east of Corfu, and twelve miles west of the coast of Albania. Its surface is highly beautiful, much enclosed, and nearly covered with olive trees. Its capital, St Gago, contains a great proportion of the population, amounting to 3948 persons, who depend very much on trade for their subsistence. Antipaxo, an islet five or six miles in circumference, and inhabited by a few fishermen, lies near it.[2]

Leucadia. Santa Maura, about twenty miles long and eight or nine broad, lies so close to the coast of Greece that it was formerly joined to it by an isthmus. It is sixty miles south-east from Corfu, three miles from Ithaca, and five from the nearest point of Cephalonia. The surface consists of a range of limestone mountains, which rise to the height of nearly 3000 feet, and terminate on the south-west in the celebrated Leucadian promontory, where unhappy lovers, following the example of Sappho, came to cure themselves of an unrequited passion. The cliff is not very lofty, though sufficiently so for the purposes of despairing lovers. It is still the custom of the neighbouring mariners, when passing, to throw in a small piece of money as an expiatory offering. The island contains very little level surface. Its principal products are olives and vines; and salt is made on the coast. The capital, also named Santa Maura, containing 5000 inhabitants, is situated at the northern point of the island, where it is separated by a narrow channel from the continent. The ancient name, Leucadia, or, as it is now pronounced, Lefcadia, is still known among the inhabitants, and ought to be used to distinguish the island from its capital.[3]

Ithaca. Theaki, the ancient Ithaca, the regal seat of Ulysses, consists merely of a narrow ridge of limestone, seventeen miles long and four in extreme breadth, rising into rugged eminences, with scarcely a hundred yards of continuous level surface in its whole extent. Near the middle it is intersected by a deep bay, which penetrates four miles inwards. Upon this bay the town of Vathi, the capital, is situated, containing 2000 inhabitants. The chief produce of the island is currants; but it yields also a small quantity of oil and wine, the latter much esteemed. The grain raised suffices only for three months' consumption. On a hill near Vathi are some massive ruins of ancient walls, with a number of sepulchres, which are supposed to mark the site of the capital of Ulysses. Near the south-east end of the island is a cliff called Koraka at present, and supposed to be the rock Korax, mentioned in the Odyssey; and under it, in a secluded and picturesque spot, is a fountain, conceived to be that of Arethusa, where Ulysses met the faithful Eumæus. The island is still named Ithaca by the more intelligent natives, which is corrupted into Theaki by some of the lower classes. Between Ithaca, Santa Maura, and the continent, are situated four small rocky isles, named Meganisi, Calamo, Atako, and Carto, besides several minute islets, of little or no importance.[4]

Ionian Islands.

Cephalonia. Cephalonia, three miles from the nearest point of Ithaca, is the largest of all the Ionian Islands. Its greatest length is forty English miles, and its greatest breadth twenty-four. A lofty chain of mountains, the Mount Ænos of antiquity, nearly 4000 feet high, occupies the centre of the island, and sends off branches to all the principal promontories. The wood which covered a part of these hills was wantonly burnt, about twenty years ago, during some internal disturbances. A deep gulf penetrates far inland from the south side of the island; and, upon the east side of this gulf stands Argostoli, the capital, containing 4000 inhabitants. Lixuri, the only other town, contains 5000 inhabitants; and there are in the island 175 villages.[5] The surface of Cephalonia is generally rocky; the soil thin, and less fertile than that of Zante. Its chief productions are currants, oil, and wine. Some ruins of Cyclopian walls mark the site of the city of Samus, mentioned by Homer; and there are some remains of Krani, Pronos, and other ancient cities. Vestiges of the altar of Jupiter Ænesius are said still to exist on the top of Mount Ænos.[6]

Zante. Zante, which lies ten miles south from the nearest point of Cephalonia, is about sixty miles in circumference. Unlike the neighbouring islands, its surface consists chiefly of a large plain, reaching from the southern to the northern coast, but bounded on the east and west sides by calcareous ridges about 1200 or 1300 feet high. This plain, covered with vineyards and olive groves, with only a few spots in tillage, presents the appearance of luxuriant fertility, and has procured for the island the title of the "Garden of the Levant." The capital, Zante, situated on the eastern side of the island, contains 18,000 inhabitants. Zante contains very few antiquities; and, though smaller and inferior in population to some of the other islands, is the richest of them all.[7]

Cerigo. Cerigo, the ancient Cythera, the last of the seven islands, is about fifty miles in circumference, and is situated near the south coast of the ancient Laconia, 150 miles from the nearest of its Ionian confederates. The face of the island is mountainous, and, though reported to be the birth-place of Venus, it is rugged, barren, and destitute of beauty. Its productions are similar to those of the other islands, but it is less commercial; and, abounding more in pasturage, it raises a considerable number of sheep and cattle.[8]

Agriculture. Landed property, in all the islands, is in the hands of a comparatively small number of persons, who form a proud, oppressive, and rapacious aristocracy. The Venetian senate, whilst it possessed these islands, kept all the more solid advantages to its own citizens, but bestowed titles, which cost nothing, profusely upon the petty insular chieftains; and nobles, destitute of education, honour, or property, are as common here as in Italy. The lands are generally let by the year, the tenant paying half the produce to the landlord; a species of tenure almost universal in rude countries. In Cephalonia, where property is pretty much divided, the largest proprietor has not above L.800 or L. 900 a year; but in Zante there are estates of more than double this value.[9] In the rural economy of the Ionian Islands, corn is an object of secondary importance, and farming is conducted on the rudest principles. Barley, wheat, maize, and oats, are cultivated, but the quantity of grain of all kinds raised does not exceed one half, and in some of the islands is not one third, of the annual amount of consumption. Of the corn raised in Ithaca, one tenth is wheat and nine tenths barley. The

Ionian Islands.

returns of the former are estimated at six or seven, and of the latter at eight or nine, for one.[1] Flax and cotton are cultivated to a small extent in several of the islands. Cephalonia is computed to yield of the latter 100,000 pounds annually, of an excellent quality.[2] The number of oxen, sheep, and goats, is considerable in the islands less adapted to the cultivation of the currant, vine, or corn; but others, such as Zante, have very few, and all are partly supplied with cattle and poultry from the Morea. Milk cows are rare, the milk of goats being preferred for ordinary use, as well as for the manufacture of cheese. The produce of wax and honey in some of the islands is very great. Cerigo is stated to have had 1280 hives in 1811, and 60,000 or 80,000 pounds of honey of an excellent quality are collected annually in Cephalonia.[3]

Olives.

The cultivation of vines and olives is an object of greater attention to the inhabitants than that of corn, and is more skilfully conducted. Nine sorts of olives grow in Zante, differing considerably in their qualities. The fruit begins to ripen in November, but does not fall off till towards the end of December or the beginning of January. This is the time when they are gathered, but in some places they are plucked with the hand, and not allowed to fall. They are carried to the mill in April, but the harvest is not entirely at an end till the month of May. The oil is carried to the sea-ports in sheep-skins. Olives are cultivated to the greatest extent in Corfu, where the produce collected every two years amounts, in middling seasons, to 700,000 jars or 90,000 barrels[4] annually. Zante produces about 30,000 barrels; Cephalonia, 30,000; Leucadia, 3000; Paxo, 8500; and Ithaca, 1500. Including Cerigo, the annual produce of olive oil will not be much less than 200,000 barrels. While the Venctians were masters of the island, and retained a monopoly of the oil trade, the price averaged from forty to forty-three livres of Corfu (6s. 8d. to 7s. 2d.) per jar; but in 1802 it rose to sixty livres (10s.); and in 1807 (a dear year) was seventeen and a half dollars per barrel, or about 19s. per jar. The oil is of four different qualities, the finest of which is fit for the table, and the other three species are used in various manufactures.[5]

Grapes.

Wine is made in all the islands to a small extent. In Zante, forty species of grape are distinguished, but the small black species, known under the name of currants, is the only kind extensively cultivated. Ithaca produces about 12,000 barrels of wine annually, of a quality superior to that of the other islands, and which sells at about twenty dollars per barrel. Cephalonia produces from 30,000 to 35,000 barrels of good wine. Zante yields only about 4000 barrels; Leucadia 1000. The produce of the other islands is not known.[6] Oranges, lemons, and citrons, are raised in several of the islands, both for domestic use and exportation; and salt is supplied for exportation in large quantities from Corfu and Leucadia.

Currants.

The currant is the staple produce of Zante, where it occupies nearly two thirds of the cultivated land. It is raised also in Cephalonia and Ithaca, but does not succeed in Corfu or Leucadia. Its culture is conducted with great neatness, and when the flower is out, the aspect of the great vineyards is singularly rich and beautiful. It thrives best in a deep rich soil, at the foot of mountains. The currants are gathered about the beginning of September, somewhat sooner than other grapes; are spread abroad for eight or ten days, and are usually ready for packing by the end of September. The annual produce of Zante is from 7,000,000 to 8,000,000 pounds, the price of which in the island varies from 14s. to 18s. per hundredweight. Cephalonia yields from 5,000,000 to 6,000,000 pounds, and Ithaca 500,000. The whole produce of the Ionian Islands in this article may therefore be estimated at 13,000,000 or 14,000,000 pounds.[7]

Annual produce.

Mr Williams gives the estimated value of the annual produce of the three islands, Zante, Paxo, and Ithaca, in corn, wine, oil, currants, honey, and flax, the chief productions, but excluding minor articles, such as cheese, fruit, &c. The estimates appear to be official, and as they are probably deduced from surveys made for the purpose of taxation, they are entitled to some degree of confidence; but it would have been more satisfactory had he stated upon what basis they were formed. The annual produce of Zante, in 1815, is stated at 1,066,145 dollars, or L.234,000; that of Ithaca, 98,896 dollars, or L.22,000; that of Paxo, 104,018 dollars, or L.23,000. These three statements give, on an average, L.6 sterling of produce for each inhabitant; but as some of the other islands are less favourably situated, L.5 is probably high enough as a mean; and if we compute the annual value of the produce of the whole on this principle, it will be L.970,000,[8] or, in round numbers, L.1,000,000 sterling; and this is exclusive of what is derived from commerce and the mechanic arts.

Commerce.

The situation of the Ionian Islands gives them naturally, and in some measure necessarily, a commercial character. Their position near the coast of Greece, where the tyranny of the Turks renders property so insecure, tends to make them a medium of communication with that country, and an entrepôt for its commodities. The narrowness of their territories, which obliges them to import provisions, and the peculiar nature of the soil and climate, which are better adapted to raise other productions than corn; their insular situation, and long connection with the Venetians; all dispose them to engage largely in commercial transactions. The trade of the islands, considering their extent and circumstances, is, in truth, considerable, and has increased greatly since it was freed from the shackles imposed upon it by the monopolizing spirit of the Venetians. The exports consist of olive oil, currants, wine, honey, wax, salt, soap, oranges, lemons, tobacco, cheese, &c. The imports are corn, woollen, cotton, and linen goods, velvets, cured fish of various kinds, sugar, coffee, iron, lead, dyestuffs, paper, drugs, spices, &c. Zante, in 1815, exported goods to the value of 591,000 dollars. Cephalonia has 250 vessels of various sizes. The little island of Paxo has 56 vessels, and exported goods to the value of 96,000 dollars in 1815. Ithaca, in 1815 or 1816, had 3598 tons of shipping, which, with boats belonging to the island, employed 823 men, and 74,360 dollars of capital. The little island of Cerigo, the least commercial of the whole, had, in 1809, only about twenty-five vessels, nearly all boats, employing 230 men. The number of Ionian vessels that trade with Turkey was estimated, in 1816, at 250, of which 200 were under their own flag, and fifty under the Russians. We should probably not err much if we estimated the exports of the whole islands at something more than double those of Zante, or about one third of the computed gross produce of the land, namely, L.300,000 sterling. A great number of their vessels trade with the Russian ports in the

[4] The barrel rather exceeds the millerole of Marseilles, or 59·7 *litres* (Vaudoncourt); and, according to Williams, is equal to 128 English pints. These accounts agree, and the barrel may therefore be considered as one fourth of a hogshead.

Black Sea, for corn; others with Malta, Greece, Italy, France, and Spain. In the intercourse between the islands which lie near one another, a species of long, slender boat is used, named *Monoxylon,* made of a single piece of wood, preserving both the form and the name of the vessels used in the earliest and rudest stage of Greek navigation.[1] The interest of money, in common cases, is ten per cent. The merchants are generally poor and unenterprising, but a few individuals have accumulated considerable fortunes.[2] One individual, a nobleman, is mentioned, who is said to possess a million of dollars. If these islands continue to enjoy tranquillity, and if their internal economy is improved, it is probable they will attract a considerable part of the trade which now centres in Salonica, Hydra, Specchia, and other Turkish ports, where the merchants are exposed to loss and vexation from the rapacity and violence of the Turkish government.[3]

Public Revenue.

The public revenue arises from a tithe or impost on the various species of produce raised within the country, grain, wine, oil, flax, and cattle; from a tax on hearths or inhabited houses, a tax on oil presses, and from duties of customs on articles exported and imported. The produce of these various duties, in 1815, was as follows:

REVENUE.

	Eventual Revenues.	Fixed Revenues.	Totals.
	Dollars.	Dollars.	Dollars.
Zante	71,779	83,015	154,795
Cephalonia	79,807	8,387	88,194
Leucadia	2,011	36,271	38,283
Ithaca	1,976	6,693	8,669
Paxo	240	6,717	6,957
Cerigo	130	5,570	5,700
Parga	35	1,623	1,667
	155,978	148,285	304,265

EXPENDITURE.

	Dollars.
Zante	102,688
Cephalonia	64,174
Leucadia	34,973
Ithaca	5,403
Paxo	6,107
Cerigo	1,956
Parga	4,267
	219,568, equal to L.48,500.
Revenue	304,265
Surplus	84,698[4]

This small expenditure appears to include only the charges of the civil government, and perhaps not the whole of these. The body of 3000 troops, chiefly British, kept in the islands, would alone evidently absorb a larger revenue. And although it was fixed by the constitution that the islands should defray the expense of their own military establishment, it appears, in point of fact, from a parliamentary paper (dated 25th of February 1820, No. 87), that the British government incurred an expense of L.145,203 in the Ionian Islands in 1817, and L.120,045 in 1818, for purposes chiefly military, but partly civil. It is difficult to conceive that there can be any British objects in that quarter requiring such an expenditure, or that the money has been advanced provisionally, to be afterwards repaid, since the revenues of the islands must now be on a permanent footing. There remains but one admissible supposition, that these islands are to form a permanent burden on the people of Britain; and yet, at a period when our own expenditure presses so heavily, it seems little less than infatuation to increase our difficulties gratuitously, by relieving a distant country, less heavily taxed, of the expense of defending itself.

Constitution.

The existing constitution of the Ionian Islands, which was sanctioned by its own legislative assembly in 1817, vests the supreme power in the high commissioner, the senate, and the legislative assembly, which have jointly the title of the Parliament of the Ionian Islands. The legislative assembly consists of forty members, of whom twenty-nine are elective and eleven *integral,* and all must belong to the class of *synclitæ,* or nobles, the common people having nothing to do with the laws but to obey them. The eleven *integral* members consist of the president and members of the old senate, with the regents or governors of the five largest islands, all of whom are substantially, though not directly, nominated by the high commissioner. The twenty-nine elective members are chosen by the nobles of the different islands, from prepared lists sent down by the primary council, in the following proportions:

Corfu	7
Cephalonia	7
Zante	7
Leucadia	4
Ithaca	1
Cerigo	1
Paxo	1
	28

And each of the last three in rotation elects a second member, which makes twenty-nine. The legislative assembly elects its own officers, fixes the amount of the supplies, and all its members have the power of proposing new laws or regulations.

The primary council, mentioned above, which acts only during a dissolution of parliament, consists of the president and members of the last senate, with five members of the last legislative assembly, nominated by the high commissioner.

The senate consists of five members and a president, the latter appointed directly by the high commissioner. The five members are elected by the legislative body out of its own number, and confirmed by the high commissioner. If he negative the election of an individual, another is elected; and if he negative the second also, the vacancy is filled up by his nominating two individuals, of whom it then falls to the legislative body to choose one. This senate is an executive council as well as a deliberative body. It nominates most of the officers under the general government, such as judges, regents, archivists, &c.; but its nominations must be confirmed by the high commissioner. It makes regulations during the recess of the legislative assembly, which have, *pro tempore,* the force of laws; and it deliberates and decides upon all propositions submitted to it by the high commissioner, or sent up from the lower house, but its members have not a power to initiate legislative proceedings.

Ionian Islands.

The legislative assembly and the senate are elected for five years, but may be dissolved at the lapse of a shorter period by the high commissioner. The appointments of judges, regents, and other officers, are also for five years.

The high commissioner is nominated by the protecting sovereign. He appoints the president of the senate, who has the initiative of all proceedings in that body. He appoints a resident for each of the islands, who has the power of suspending any proceeding of the local government. He nominates a number of officers, and has a negative, direct or indirect, upon the appointment of most of those whom he does not nominate. He has a *veto* on all propositions which have passed the two houses; but though he give his sanction to any specific measure, there is still another *veto* behind, lodged in the king of Britain, who may annul the proceeding at any period within one year of its enactment.

Each island has a local government, consisting of a municipal council of five members, selected by the regent (with the approbation of the high commissioner), out of a list of ten, chosen by the *synclitæ*. And besides these, there are five active functionaries, a regent, secretary, fiscal, archivist, and treasurer, all, except the last, nominated by the senate, and confirmed by the high commissioner.

The judicial power is lodged in a supreme court at the seat of government, consisting of four ordinary and two extraordinary members. Of the former, two are native Ionians, named by the senate, and approved of by the commissioner; and two, directly named by the commissioner, may either be British subjects or Ionians. When these four are equally divided on any question, reference is made to the two extraordinary members, who are the high commissioner and president of the senate. Subordinate to this supreme court are twenty-one inferior tribunals, that is, a civil, a criminal, and a commercial tribunal in each island. And under these, again, are justice of peace courts, for minor offences, and small civil suits. Besides the general appellant jurisdiction which the supreme court has over the local tribunals, it is empowered to send a delegation of its members on circuit on special occasions, when thought necessary by the senate and high commissioner. The number of judges in the local courts is not fixed by the constitution.

The *sanita*, or health establishment, is under the sole direction of the high commissioner. The army, consisting entirely of the troops of the protecting sovereign, is also under the orders of his representative. The expense of the army is to be defrayed by the islands if the number does not exceed three thousand men. There is, besides, a national militia, commanded by native officers.

Individuals, or bodies of men, have the right of representation or petition to the protecting sovereign or his ministers.

We have described this constitution more in detail than its importance merits; for, without exaggeration, it may certainly be pronounced to be the very worst among the numerous plans of representative government framed within the last thirty years. It is, in fact, little else than a compact between the British government and the petty despots of the islands, settling in what proportions the power, patronage, and taxes of the country are to be shared between them. The rights and interests of the mass of the people, for which even the German princes in their new constitutions profess a decent respect, are not the object of one single stipulation in this long and detailed instrument.

The style of building in the Ionian Islands is chiefly Italian, and the interior of some of the cities shows great neatness. The streets are generally narrow; the houses, some of wood, some of stone, are three, four, or even five stories high, with open latticed windows. The shops are tolerably well supplied with manufactured and colonial articles; and the persons employed in them display more alertness and civility than the indolent shop-keepers of Spain, Portugal, and Sicily. The churches, as in Greece, are disproportionately numerous. Some of them have steeples, others have merely an elevated façade. The population, in consequence of the long dominion of the Venetians, is, in manners and habits, as well as in costume and language, intermediate between the Greek and Italian character. Though enjoying more liberty, they are, in some respects, inferior to the continental Greeks. Their exterior is less dignified, their manners more corrupt, and they show less capability of again becoming a people. This degradation of character may be attributed chiefly to the vicious nature of the Venetian government. The governors and judges whom it sent out to the islands were very often nobles of decayed fortune, who undertook the duties as a speculation to retrieve their affairs. Bribery was practised openly; toleration for a crime might easily be purchased; and the laws, imperfect in themselves, were rendered wholly null by the corruption of the judges. The petty insular aristocracy separated into factions, which trampled on the laws and oppressed the people. The Venetian government, by a detestable policy, encouraged their feuds to prevent their combination, and exposed the country to all the evils of a continued civil war. As happens in all countries where justice is denied by the laws, private revenge and assassination prevailed to a frightful extent. In the island of Zante alone, with 33,000 inhabitants, the number of assassinations sometimes exceeded one for each day of the year. Many of the nobles, indeed, kept assassins in their pay; and others of them fitted out privateers for the trade of general piracy, in which the vessels of their own countrymen were not spared. These nobles are generally educated in Italy, and speak the Italian language; but in knowledge and refinement they are scarcely on a level with the middle ranks in England. The lower classes, like the continental Greeks, use the Romaic language, but with a larger mixture of Italian words; and, like them, too, they are active, ingenious, adroit, loquacious, subtle, and intriguing. Physic and law are favourite professions, and the better order of lawyers and physicians, who have been educated in Italy, form the most intelligent part of society. The clergy are extremely numerous, but less informed, and inferior in respectability to the two former classes. They were very active in resisting some of the reforms attempted by the British. When Major du Bosset introduced the culture of the potato in Cephalonia, they laboured to persuade the peasants that this was the very apple with which the serpent tempted Adam and Eve in paradise.[1] The women, as in Greece, are almost entirely secluded from society, and are, of course, ignorant, superstitious, and feeble in their character.[2] In all that regards the intercourse of the sexes much laxity of morals prevails, but the poor are less corrupted than the rich. Most of the nobility have mistresses, and the laws allow them to legitimate the issue of these connections by a subsequent marriage. A sort of agreement is not unfrequent, by which a young woman is made over by her parents, with her own consent, to her admirer, at a stipulated sum. This species of concubinage, which frequently terminates in marriage when the girl is respectable and has children, is, on other occasions,

Manners and customs.

Ionian Islands.

the cause of much infidelity and unhappiness.[1] In the country the Greek dress is generally used, though with some modifications; but in the towns the Italian dress prevails, as well as the Italian fashions in the style of furniture and in the modes of social intercourse. It was a leading object in the policy of the Venetians, indeed, to extinguish the national spirit of the Ionians, to deprive them of the means of education, and to brutalize their character by every method in their power, that they might convert them into passive instruments of their sovereign will. But, after three centuries of such policy, there can be no doubt that the Venetians lost more by the odious nature of the innovations attempted than they gained in security by the result.[2]

The attachment of the Ionians to the Greek religion, however, has effectually resisted the innovating spirit of their masters. The Catholic worship is tolerated, but the national faith has lost little of its influence upon the minds of the people. Each island has its patron saint, in the efficacy of whose intercession the people are taught to believe. The British authorities humour the popular superstition in this particular; and, in Corfu, the patents from the health office bear to be "in the name of God, and by the intercession of Saint Spiridion." Ceremonies and processions, with fasts, frequent and severe, take the place of piety and good works. A ruffian engaged in a project of assassination has refused to taste animal food during the season of the fast. As in many other countries, the lower orders are comparatively strict in their religious observances, while indifference and infidelity are common among the higher classes. But, if religion is in a low state, it is not from the want of priests and churches, the number of which is out of all proportion to the number of inhabitants. The little island of Paxo, with 4000 inhabitants, has thirty-six churches; and Cerigo, with 9000 inhabitants, is said to have the incredible number of 260 churches or chapels, and 165 priests. These swarms of priests are a sort of privileged mendicants. They are, in general, too illiterate to understand religion themselves, and, of course, they are incapable of teaching it to others. But as they derive their subsistence chiefly from fees for absolution, and from gifts and offerings, they find it necessary to support their influence by filling the minds of those under their care with a thousand idle or pernicious superstitions. Besides the secular clergy, there are a number of regular religious in convents scattered over the islands, but of their number or condition we have seen no satisfactory account.[3]

The Ionian Islands make no considerable figure in ancient history. Cephalonia, Zante, Ithaca, and Santa Maura (then joined to the continent), formed part of the kingdom of Ulysses; and, if we may judge of their condition from the armament which their prince carried with him to the Trojan war, we should conclude that they were less populous and less improved than the continental parts of Greece. These islands, along with a part of the opposite continent, furnished only twelve ships, whilst the little island of Salamis, not one twentieth part of the extent, sent as many.[4] They were then, as at this day, under the power of a number of petty chieftains; and it is a proof of the accuracy of Homer's geographical knowledge, that their relative numbers, as stated by Telemachus,[5] correspond tolerably well with the actual extent and importance of the islands, Cephalonia having twenty-four, Zante twenty, and Ithaca twelve. At a later period, the Corinthians planted colonies in Leucadia and Corcyra, and probably in some of the other islands over which they maintained some degree of authority. The Leucadians sent 800 men to fight the Persians at Platæa, and the Cephalenians of Pale 200.[6] The Corcyreans, from their favourable situation, rapidly became strong by sea, and not only shook off their dependence on the parent state, but committed depredations on the commerce of the other Grecian cities, till the Athenians, shortly after the battle of Marathon, attacked them and broke their naval strength. The jealousy between the Corcyreans and Corinthians, about forty-five years later, led to hostilities between the parties, in which the Athenians were drawn in to take the part of the former; and the extension of this petty quarrel at length produced the celebrated Peleponnesian war. The Corcyreans had 120 triremes when the contest began, and were the second naval power in Greece.[7] The Zacynthians also, who were a colony of Achæans, and the Cephalenians, were generally leagued with the Athenians, and afforded them assistance in the expedition against Syracuse. The Leucadians we find adhering to the Corinthians.[8] When the Spartans invaded Corcyra, about thirty years after this, the country is represented as richly cultivated, finely planted, and abounding in wealth and luxury.[9] Cerigo, from its situation, was almost always an appendage to Laconia. These islands, with the rest of Greece, at length fell under the dominion of the Macedonians. In the wars between Philip and the Ætolians, however, we find the latter occasionally making use of the naval forces of the Cephalenians.[10] When the Romans established themselves in Greece, these isles, from the position between that country and Italy, were early occupied; and Corcyra is often mentioned as a station of their fleet in their subsequent wars.[11] They continued to follow the fortunes of the Roman empire nearly to the latest period of its decline; and they suffered from the ravages of the Goths, Wallachians, and other barbarous tribes, till they fell into the hands of the Venetians, some of them in the twelfth, and others in the thirteenth century. This nation also conquered various maritime towns on the continent of Greece, of which, as well as of some of the islands, the Turks occasionally dispossessed them. The Venetians first acquired the Morea in 1417, and lost it finally in 1715. The Turks, at this latter period, took Cerigo, and besieged the city of Corfu; but the Venetians becoming masters at sea, regained Cerigo, repulsed the Turks from Corfu, and took several continental towns.[12] The treaty of Campo Formio (October 1797), which annihilated the state of Venice, transferred to France the Ionian Islands, with their continental dependencies, consisting, at that time, of five sea-port towns, Butrinto, Gomenitza, Parga, Prevesa, and Vonitza. When the invasion of Egypt led to hostilities between France and Turkey in 1798, Ali, pasha of Albania, besieged and took Prevesa and the other continental towns, except Parga; and the islands, having been reduced by the fleets of Russia and Turkey, were erected into an independent state, by a treaty between these powers, dated 21st March 1800. They were placed under the protection of the Porte, as its vassals, and were to pay it an annual sum of 75,000 piastres.[13] The towns on the continent were ceded to the

Ionian Islands.

Porte, of four of which it obtained possession. But the inhabitants of Parga, dreading the merciless disposition of the Albanian pasha, took up arms in their own defence, and, favoured by the strength of their position, repelled his assaults. A constitution was given to the republic in 1803, which it is unnecessary to describe, as it has since been superseded. It is sufficient to say, that it was drawn up by Russian ministers of state, ignorant of the circumstances of the islands, and contained such a specimen of republican principles as might be expected from Muscovy. The war between Russia and the Porte in 1806 led to the occupation of the Ionian Islands by the former; but by a secret article of the treaty of Tilsit (June 1807), they were made over to France. The French, during their first occupation of the islands, had abolished the use of the Italian language in public acts, and re-established the Romaic. Connecting these possessions with his projects against Turkey, Napoleon was anxious to revive the national spirit of the Greeks. A Romaic newspaper was set on foot, and has been continued by the British; establishments for promoting scientific education were projected; and, to crown these schemes by a piece of French extravagance, the reckoning by olympiads was introduced. These projects held out only a distant prospect of good, but the expense of the large military force stationed by the French in the islands was a real and immediate grievance. In 1810, a British force, under General Oswald, took possession of Zante, Cephalonia, Ithaca, and Cerigo, almost without opposition; and also of Santa Maura after some resistance. Corfu and Paxo having garrisons too strong to be attacked, were merely subjected to a maritime blockade, which, however, could not be so rigorously enforced as to reduce them. They were surrendered to the British after the general peace in 1814. The Turkish government now renewed its claim to Parga, under the treaty of 1800, though that claim had been virtually set aside by subsequent circumstances. That government had entirely failed in affording the Ionian Islands the stipulated protection, since it had suffered first the Russians, and afterwards the French, to occupy them with a military force. It had been a party to subsequent treaties, by which this had been in substance annulled. The original treaty bound the Turks to protect the Parguinotes; and it was now obvious, from the fate of the other towns, and from the feelings of the inhabitants, that its surrender would be equivalent to a warrant for its destruction. Lastly, the British had no right to make over Parga to the Turks, for it was not reduced by our arms, but its inhabitants put themselves under our protection by a voluntary act, and upon the express condition that their town was to remain attached to the Ionian republic. From ignorance or inattention to these circumstances, however, the Congress of Vienna had resolved that Parga should be given up. And, in obedience to the mandate of this conclave of sovereigns, the soldiers of Ali took possession of the bare walls in June 1819; the inhabitants, amounting to 5000, having, to a man, emigrated to Paxo and the other islands, after receiving a very inadequate indemnity for the loss of their property.[1]

General remarks.

The Ionian Islands, either as a separate state or as a dependency of Great Britain, are of little importance. The interest felt in their fate was founded partly on classical associations, and partly on the means they were supposed to afford for restoring the Greeks to their existence as a nation. But, under the political system established in the islands, the hopes raised on the latter ground proved almost entirely chimerical. The Ionian Greeks must be enlightened and improved themselves before they can become useful auxiliaries in the work of enlightening and improving the rest of their countrymen. To effect this change in their character, and to create and nourish a national spirit, three things are indispensable, with which their new constitution leaves them entirely unprovided; a system of national education, a free press, and a free government. The British ministry, in patronizing a plan for erecting a university in the islands, began its operations at the wrong end. The first and most indispensable step is to increase the small number of schools at present in existence, till they become sufficiently numerous to afford common education to the whole population. A university may then be useful; but the Greeks can never be enlightened by giving a learned education to a few individuals, whilst the mass remains sunk in ignorance and superstition. On the other hand, when a moderate degree of knowledge is generally diffused, ardent spirits will emerge from the multitude, and rise to eminence by their native force, while their countrymen will then be better prepared to reap advantage from their exertions. At present a well-informed Greek finds his acquisitions useless. Again, without a free press in their native language, the Greeks cannot receive that political instruction which is necessary to fit them for becoming once more a nation; knowledge cannot be rendered popular, nor of course useful; and a university will become a mere establishment of sinecures, or an engine for propagating corrupt and servile doctrines, worse than ignorance itself. It is no solid objection that the Ionian Greeks are mere children in literature, and could not make a discreet use of the press. Feeble as their powers may be, they will continue children still, if they do not use them. Their own blunders will often be better instructors than the mature wisdom of others. With general education and a free press, should be conjoined the invigorating spirit of a popular government; not a government bottomed on close corporations and privileged classes, but one broadly republican in its forms and spirit. Whatever may be the defects of such a government, it is calculated, beyond all other human inventions, to call forth the energies of man. It was this inspiring power that carried forward the ancient Athenians in their brilliant career of improvement and glory; that raised the Italian and Dutch republics to sudden wealth and power; and that is already giving a new aspect to the vast continent of North America. The people are ignorant and disorderly, but probably not more so than the Athenians in the time of Solon, or the Italians in the thirteenth century, who were, nevertheless, found capable of supporting republican institutions. The errors into which their ignorance might have led them would most probably have soon cured themselves. And, at any rate, the Ionians are in that precise situation which would have divested such institutions of the dangers usually supposed to attend them. The natural influence of the British government, as the protecting power, would have moderated the violence of factions, and preserved the government stable amidst their struggles. Had a free, active, and enlightened community been raised up in these islands, speaking the language of Greece, and almost in contact with the country, the emancipation of the continental Greeks would not only have been secured by the joint operation of moral and political causes, but so much light would have been diffused among them, and such a good model set before them, that they would have been in a condition to make a wise and safe use of their independence, and step at once into the enjoyment of a free constitution. As matters have been managed, however, it would be foolish to expect that these islands will contribute

[1] *Edinburgh Review*, No. lxiv. art. i.; Holland's *Travels*, chap. ii.; Treaty between Britain and Russia, 5th November 1815.

in any material degree to the improvement of the Greeks. Exclusively of the prerogatives of the high commissioner, all power is vested in the nobles, who are universally described as the most worthless part of the population. Votes alone will command office; and the mass of the people, who have no votes to give, though not expressly, will yet be substantially excluded from every place of trust and honour, and kept in the same state of vassalage as under the Venetians. Public burdens will naturally accumulate, because those who impose taxes have a separate interest from those who pay them; and abuses will multiply, because the nobles, hanging on the government for support, are gainers by a system of waste and profusion. A free press, which would have corrected some of these evils, has been jealously guarded against by the constitution; and as for the right of petition, in a government so constructed, it must be an empty name. In all probability, then, the Ionians will consider the Turkish practice of insurrection as the only effectual method of making known their grievances. Accordingly, since the new constitution was promulgated in 1817, several attempts at insurrection have been made. But whether these have originated in the factious spirit of the nobles, or the discontents of the body of the people, has not been clearly explained. Yet though but little comparatively has been done for the people, the change has certainly been for their advantage. The administration of justice has improved; the private wars and open rapine of the nobles have been restrained; and the powers taken from these persons, and conferred on the commissioner, have been more beneficially exercised for the inhabitants at large. But a much more stable foundation would have been laid for good government, had the people been furnished with constitutional rights to protect themselves, even although they had not made a very wise use of those rights in the first instance.

IONIC ORDER. See ARCHITECTURE.

IONIC Dialect, in *Grammar*, a manner of speaking peculiar to the people of Ionia.

IONIC Sect was the first of the ancient sects of philosophers; the others were the Italic and the Eleatic. The founder of the Ionic sect was Thales, a native of Miletus, in Ionia, whence his followers assumed the appellation of *Ionic.* Thales was succeeded by Anaximander, and the latter by Anaximenes, both of Miletus. Anaxagoras Clazomenius succeeded them, and removed his school from Asia to Athens, where Socrates was his scholar. It was the distinguishing tenet of this sect that water was the principle of all natural things.

IONIUM MARE, a part of the Mediterranean Sea, at the bottom of the Adriatic. It lies between Sicily and Greece. That part of the Ægean Sea which lies on the coasts of Ionia in Asia is called the *Sea of Ionia*, and not the *Ionian Sea.* According to some authors, the Ionian Sea receives its name from Io, who swam across after she had been metamorphosed into a heifer.

IPHICRATES, one of the most celebrated generals of the Athenians, was a man of low origin, who raised himself to the highest rank by his prudence and military talents. The exact date of his birth and death is unknown; but he began to take an active part in the affairs of his country in 392, B. C. when he proceeded with Conon to oppose Agesilaus, who began to threaten the independence of Athens. At this time he defeated a *mora* of the Lacedemonians, a body of men then the most active and vigorous in Greece. (Xen. *Hell.* iv. 5, 11–18.) On the death of Thrasybulus, B. C. 389, Iphicrates was appointed to succeed him in the command of the troops on the Hellespont, and there laid siege to Abydos, which was commanded by Nicolochus, the Spartan general; but the result of the siege is not known. (v. 1, 6–7.) For many years we lose sight of Iphicrates; nor does he again appear on the stage till B. C. 374, when we find him commanding the mercenary troops of Persia in Egypt. Next year, when Corcyra was threatened by the united fleets of Sparta and Syracuse, Athens sent to the assistance of this island a fleet of sixty vessels, commanded, first by Timotheus, and afterwards by Iphicrates. The latter, assisted by the orator Callistratus, and Chabrias, attacked and defeated the Syracusans. (vi. 2.) History again fails us, and we hear nothing more of Iphicrates till B. C. 355, when he was sent, along with Timotheus and Chares, to recover Byzantium and some other cities which had revolted. The fleet commanded by these three generals was soon in presence of the enemy; and they were preparing to offer battle when a tempest dispersed part of their vessels. Chares wished, nevertheless, that they should engage in battle, but Iphicrates and Timotheus opposed the proposal. On this account they were recalled, and, being accused by Chares and Aristophon of treachery, Timotheus was most unjustly condemned, whilst Iphicrates, who defended himself, not only by his eloquence, but by arming a number of his friends, was acquitted (Nepos, *Timoth. et Iphicr.*) From that time he quitted the military service of his country. He was married to the daughter of Cotys, king of Thrace, and had by her a son named Menestheus.

IPHIGENIA, a daughter of Agamemnon and Clytemnestra. When the Greeks, going to the Trojan war, were detained by contrary winds at Aulis, they were informed by one of the soothsayers, that to appease the gods they must sacrifice to Diana, Iphigenia, daughter of Agamemnon. The father, who had provoked the goddess by killing her favourite stag, heard this with the greatest horror and indignation; and, rather than shed the blood of his daughter, he commanded one of his heralds, as chief of the Grecian forces, to order all the assembly to depart each to his respective home. Ulysses and the other generals interfered, and Agamemnon consented to immolate his daughter for the common cause of Greece. As Iphigenia was tenderly loved by her mother, the Greeks sent for her on pretence of giving her in marriage to Achilles. Clytemnestra gladly permitted her departure, and Iphigenia came to Aulis, where she saw the bloody preparations for the sacrifice. She implored the forgiveness and protection of her father, but tears and entreaties were unavailing. Calchas took the knife in his hand, and, as he was going to strike the fatal blow, Iphigenia suddenly disappeared, and a goat of uncommon size and beauty was found in her place for the sacrifice. This supernatural change animated the Greeks, the wind suddenly became favourable, and the combined fleet set sail from Aulis.

IPSWICH, a market and borough town, the capital of the county of Suffolk, sixty-nine miles from London. It stands on the side of a gentle elevation rising from the banks of the river Orwell, which is navigable for vessels of the smaller size to the bottom of the town. The country around it is fertile, and the banks of the river present most pleasing prospects. It is a place of great antiquity, and many of the houses still bear marks of their ancient erection. The streets are well paved; and there is a good market-place, well frequented four days in each week. It formerly contained nineteen parish churches, and still retains twelve, besides several places of worship for dissenters from the establishment. There is a town and a shire hall, and an extensive county jail. A college was established here by Cardinal Wolsey, a native of this place; but it fell with the founder. There is, however, an endowed classical school. Ipswich was formerly celebrated for its woollen manufactures, but that branch of industry has been removed to the northern counties. The chief trade at present is in building ships, and in exporting ship timber, corn, and malt; but it has a considerable import trade for wines, spirits, timber, ship-stores, and other commodities, the duty on which, in 1833, amounted to L.32,323. It is a corporate town, governed by two bailiffs chosen annually, a recorder, two chamberlains, two coroners, and twenty-four common councilmen. It returns two members to parliament, chosen by the freemen; and has an admiralty jurisdiction on the Essex coast beyond Harwich, and on the Suffolk coast to the boundary of the county. The population amounted in 1801 to 11,297, in 1811 to 13,670, in 1821 to 17,186, and in 1831 to 20,454.

IRAK, a province of Persia, being the greatest part of the ancient Media, is bounded on the south by Fars and Kuzistan; on the east by Khorassan and the great salt desert; on the west by Kurdistan; and on the north by Azerbijan, Ghilan, and Mazunderan. This great province has everywhere a most mountainous appearance. The mountains are barren and devoid of timber, and run generally from west to east, enclosing valleys from ten to fifteen miles in breadth. They either gradually sink into the desert, or throw out branches into the provinces of Kerman and Khorassan. The valleys are for the most part uncultivated, excepting in the vicinity of the villages. The land, however, is good, and is capable of yielding abundance of corn. But the country languishes under oppression, by which the valleys that were once productive are now rendered desolate; and the cities and aqueducts, which were formerly in a different condition, are now ruined. This province is divided into five great districts, and each of these into lesser districts. There are, 1*st*, Ispahan; 2*d*, Teheran; 3*d*, Naen; 4*th*, Mullager; 5*th*, Kermanshaw. A lofty range of mountains divides the northern frontier of Irak from the provinces bordering on the Caspian Sea. This range passes about six miles to the north of Teheran, and, about fifty to the east, suddenly advances to the south as far as latitude 36° north, and again as suddenly retiring, forms a point, at the extremity of which is the Pass of Khawar, designated in ancient geography by the appellation of the Caspian Gate. Some of the plains in this province afford excellent pasturage, and are populous and well cultivated, while others are almost in a state of nature. Towards the south-west, near the mountains of Louristan, the high country is diversified with rich valleys, inhabited by the tribes of Fity and Bucktiari; and the southern division of the district of Ispahan, lying between that capital and the towns of Yezdikhaust and Isferjan, is more populous than the neighbouring district of Fars, and is just recovering from the deplorable state to which it had been reduced by the ravages of the Afghans. The valleys are all connected with each other, either by openings in the mountains, or narrow defiles. The villages have a picturesque and flourishing appearance; and the produce of the district is not inferior to that of the most fertile spots in Persia. It is about seventy miles in length and forty in breadth, and is irrigated by canals cut from the Zeinderood, which are surrounded with gardens and a prodigious number of pigeon-houses. These animals are kept principally for the sake of their dung, which is a rich manure, and is supposed to give to the melons of Ispahan their acknowledged superiority in flavour to all others. The largest of these pigeon-towers sells for about L.3000. The most arid part of Irak is that situated between this city and Yezd. The soil is poor, and light, and sandy. A general scarcity of wood and water prevails; and the climate is hot, though not unhealthy. The climate of Irak towards the north is delightful in the spring, though rather cold towards its commencement, as the snow is scarcely off the ground, and a keen north wind blows from the mountains. The heat sets in towards the middle of June, and continues to increase till the middle of August, when the harvest is collected. Snow begins to fall in the end of September, and continues to fall in great quantities during the months of December, January, and February. In the province of Irak is the high land which divides the streams that flow northward into the Caspian Sea from those which flow southward; namely, the tributary waters of the Tigris, or the Shut-ul-Arab, and their head branches, one of which, the Zeinderood, passes through the city of Ispahan. Within the limits of this province are comprehended many great and celebrated cities, the largest of which is Ispahan, for many ages the capital of the Persian monarchy; Yezd, which is large and populous; Natunz; Cashan, a flourishing city; Koom; Teheran, the present capital of Persia; Casween, a commercial and populous city; Sultanea, now in ruins; Zinjan, a prosperous town; Hamadan, supposed to be the ancient Ecbatana; Kermanshaw, and others.

IRASCIBLE, in the old philosophy, a term applied to an appetite or a part of the soul, where anger and the other passions which animate us against things difficult or odious were supposed to reside.

Of the eleven kinds of passions attributed to the soul, philosophers ascribe five to the irascible appetite, viz. wrath, boldness, fear, hope, and despair; the other six being charged on the concupiscible appetite, viz. pleasure, pain, desire, aversion, love, and hatred.

IRBIT, or Irbitskaia, a town of Russia, in the government of Perm, on the river Irbit, and the frontiers of Siberia. It is noted for a yearly market held in January, the season for travelling on the ice, and is an entrepôt for Siberian furs, and other arctic merchandise passing into Europe. The annual fair is frequented by Russians and Siberians, Tartars, Armenians, and Greeks. Near it is a large iron work, which yields nearly 2000 tons of iron a year. It is 142 miles north-east of Ekaterinenburg. Long. 62. 50. E. Lat. 57. 35. N.

IREG, a market-town of the circle of Sezerem, in the Austrian Sclavonian province of Siebenbirgen. It stands at the foot of the Karlovitz Mountains, in a fruitful district yielding good wine. It contains 1020 houses, with 4863 inhabitants. Long. 19. 47. 59. E. Lat. 45. 6. 47. N.

IRELAND.

Ireland, one of the largest of the European islands, is situated to the west of Great Britain, from which it is separated by a narrow channel called the Irish Sea and St George's Channel on the east, and is bounded on its other sides by the Atlantic Ocean, through which it can maintain a direct communication with the continents of Europe, Africa, and America. The advantageous position, the fertility of the soil, and the salubrity of the climate, have conferred upon Ireland commercial facilities, which are capable of being greatly increased. How far these natural advantages have been made available towards the internal improvement of the island itself, and the general benefit of the empire of which it forms an important part, may be best ascertained from the following details of its history and statistics.

HISTORY.

The Irish nation is undoubtedly of Celtic origin. This truth is stamped in indelible characters in the names of the rivers, towns, mountains, and other objects of historical notoriety throughout the island; it is proclaimed by marks equally indelible in the relics of antiquity, the tumuli, the cairns, the cromleachs, and the druidical circles, the remains of which, after having triumphed over the ravages of time and repeated revolutions, are now perpetuated in the pages of the antiquary's researches. The name of the island itself confirms the assertion. Eri or Erin, its most ancient appellation, and that to which the natives still cling with the attachment of veneration, is derived from the Celtic Iar or Eir, which signifies western. Most of its more modern names may be easily traced to this source. By the Grecians, to whom, though unacquainted with its localities, its general geographical position and bearings were not unknown, it was called Ierna, being honoured by them with the rank of the third of the islands of the ocean, and yielding precedence in this respect only to Taprobane and Britain. Ptolemy names it Iouerna; Juvenal and Mela, Iuverna. Diodorus Siculus, approaching more nearly to the aboriginal word, calls it Iris. Marcianus Heracleota and Eustathius adopt the term used by Ptolemy, but corrupted by the latter into Bernia. By the Britons it was called Iverdon; and the Saxons, attaching to the native name an epithet from their own language, called it Ierland or Ireland. Its later name, Hibernia, may be traced somewhat more circuitously to the same source, although much etymological and antiquarian ingenuity has been employed to deduce it from other circumstances. Some choose to derive it from its climate, calling it Hibernus, on account of its wintry temperature, as unjustly in fact as erroneously in etymology; others from Iberus, a Spaniard, or a river of Spain. One writer ventures still further. Postellus, in his strictures on Mela, deduces it from the Hebrew, "Irin quasi Iurin," the land of the Hebrews, "who, knowing that the empire of the world would be established in a very strong corner to the north-west, made themselves masters as soon as possible of those parts, and of Ireland." Bochart traces it to the Phœnician; Hibernia, according to him, or Ierne, being nothing more than Ibernæ, or the furthest habitation, because, beyond Ireland westward, all was ocean, according to the ancients. This derivation may be easily made to harmonize with that deduced from the Celtic, serving also to corroborate the opinion now very generally entertained, that the Celtic Irish and the Phœnician were kindred branches from the same eastern stem. Another name from another source has been fixed upon Ireland, one of different derivation, and of later acceptation, as not being known until the fourth century after Christ, when the country was generally designated throughout the learned world of that day by the name of Scotia. Some writers take the word to be a corruption of Scythia, from which region they suppose the nation to have emigrated; others, amongst whom are Whitaker and Chalmers, assert that the people acquired this name from their habits of roving and spirit of enterprise; the term "sceite," according to them, signifying dispersed or scattered. The name of Ogygia has also been applied to it, and adopted by O'Flaherty in his *Chronological Annals*. Certainly, if the Ogygia, which Plutarch places west of Britain, be any thing more than an imaginary formation, it must signify Ireland. Yet if so, it should more properly be considered as an epithet given to it on account of its antiquity than as a proper name; the Greeks applying that word exclusively to what was of an origin beyond existing records.

A recurrence to the Greek and Roman writers will show that the country thus designated was not considered by them as the habitation of a single nation. On the contrary, its coasts are described by Ptolemy as being possessed by a number of tribes of various names; whilst with the interior he seems to have had no acquaintance. His nomenclature has been followed by succeeding geographers, with little variation. According to these authorities, the northern regions were possessed by the Venicnii and the Robogdii; the eastern by the Darnii or Darini, the Voluntii, the Blanii or Eblanii, the Cauci, the Menapii, and the Coriondi; the southern shores were possessed by the Brigantes, the Vodii, the Uterni or Ivernii, and the Vellebori; the western coast was the residence of the Gangani or Cancani, the Auteri, the Nagnatæ, and the Herdini or Herpeditani. Whitaker supposes the interior, comprehending all the inland counties, to have been peopled by a tribe which he calls the Scoti.

The native annalists present a very different picture of the ancient state of the country, which, although much disfigured by the fables of romance with which the bards, the only historians of the time, chose, for very obvious reasons, to embellish their narratives, must be supposed to rest upon a groundwork of reality. Rejecting, therefore, from their accounts what is evidently fabulous, and suspending the judgment as to circumstances of doubtful or obscure character, the temperate investigator of truth will be able to trace a series of historical connections, to which assent may be conceded, at least to the same extent as to those parts of the recognised histories of other countries, in which it is acknowledged that truth verges upon fiction. With this clue to the investigation of a train of occurrences which affect to penetrate further into the darkness of antiquity than those of any other nation, except the Jewish, the investigation of the history of Ireland may be ventured on from the earliest period at which the most enthusiastic advocate of its primeval origin thinks himself justified in fixing his first footsteps, until we arrive, through the periods of doubt, at those of undisputed historical certainty in our own times.

According to the native historians, Partholan, the sixth in descent from Magog, Noah's second son, settled in Ireland at the head of a thousand men, and took possession of a country in which no one appeared to dispute his right of occupancy. But he did not long enjoy his possession of it in tranquillity; for at the same time, or shortly afterwards, there arrived a band of lawless adventurers, of the stock of Nimrod, the descendant of Ham, who were distinguished by the name of Fomorians, or Fawmorries, a name still applied to strangers by the native Irish. With these took place a series of deadly hostilities, which terminated in a battle so bloody and so decisive, that not a single stranger was left alive; and the ground was so infected with the putrefying corpses, which the residue of the followers of Partholan were now too few and weak to inter, that a plague broke out, which destroyed all the survivors, and left the country totally uninhabited for thirty years.

At the termination of this period, Nemedius, another descendant of Japhet, made a settlement on the island with a thousand men, from the borders of the Euxine. The tranquillity of his settlement was also disturbed by the incursions of tribes of Fomorians, here said to be African pirates, with whom his followers carried on an incessant warfare, but with different ultimate success; for the strangers, being reinforced with fresh supplies from their own countrymen, at length defeated the Nemedians with such slaughter, as to force the scanty remains of this second colony to return to the country whence they had originally emigrated. They took their departure in three companies. The first, under Breac, proceeded to Thrace, where they took the name of Belgæ; the second, under Jobath, proceeded no farther than Bœotia; and the third, under Bridtan, repaired to the neighbouring island of Britain, where they formed the tribe of the Brigantes. From this Bridtan, the Psalter of Cashel, a record of great authority in the first and second ages of the Irish, traces the origin of the Welsh.

The Fomorians, when sole masters of the country, went to war amongst themselves, and carried their dissensions to such a height of animosity, that the island was a second time utterly depopulated, and continued so until some of the descendants of the Thracian Nemedians, to the number of about five thousand men, returned thither, under the command of the five sons of Dela. The Irish annalists distinguish this colony by the name of Fir-bolgs; a name said to be applied to tribes living in caves, whither the natives used to have recourse for shelter in cases of extremity. To this colony is attributed the division of the country into five principalities, which continued, though not without interruption, till the English invasion. The names of the states of the pentarchy were, Leinster, Munster, Ulster, Connaught, and Meath. The principal chieftain of each division was honoured with the title of king, a name applied very liberally at all times to the petty dynasts who arrogated supreme authority over their own territories, however limited; but the ruler over Leinster was recognised as sovereign, to whom submission was tendered, and from whom protection was claimed, by the other members of the pentarchy in cases of danger. This system of government continued undisturbed for eighty years, through a succession of nine sovereign rulers, when it was broken in upon by the intrusion of another colony of the same stock, called by the Irish writers Tuatha-na-Danans; a name said by some to have been given them as being the descendants of the three sons of Danan, a profound adept in the art of magic, and by others, as being divided into the three tribes of Tuatha or commanders, Dee, druids or priests, and Danan or bards. The chronicles of the time state, that having been driven out of Bœotia by their inveterate enemies the Fomorians, after wandering through various countries, they settled in Norway, where they were hospitably received; whence they removed to Scotland, and, after a residence there of seven years, proceeded to Ireland, carrying with them several necromantic curiosities, the most remarkable of which was the fatal stone, or stone of destiny, to which tradition attached the belief that the sovereignty would remain with that nation whose king was crowned upon it. The tale would be unworthy of historical notice, were not an observance of the present day connected with the superstitious credence to which it owes its birth. The stone, after having been preserved for many generations in the line of the Irish Milesian monarchs, was taken to Scotland by a king of that family, by whom it was fraudulently detained, and used as the inauguration stone of the Scottish kings until the time of Edward I. of England, who, on his conquest of the country, transferred it, together with all the other appendages of royalty, to London, where it is still kept, under the name of Jacob's stone, and is used in the ceremonial of the coronation of the kings of Great Britain. The Belgæ defended themselves for some time with great spirit, but they were at length totally defeated. Numbers of them withdrew to the neighbouring islands and coasts of Scotland; and those who remained were reduced to a state of abject slavery, under which they remained during the whole time their enemies held the dominion, which the latter were enabled to do, without molestation from a foreign enemy, for an hundred and ninety-seven years, under a succession of nine sovereigns.

The dynasty of the Tuatha-na-Danans was terminated by an event similar to those which had extinguished the two previous colonies. An expedition from Spain, under the eight sons of Milesius, landed in the south-west of Ireland, and after encountering many perils, partly by the violence of a storm, by which five of the leaders were lost, partly by the resistance of the old settlers, they obtained possession of the entire country, which was divided between Heremon and Heber, two of the surviving sons of Milesius; Amergin, the third, having no share in the government, but acting rather as a councillor to both, a function which his literary acquirements entitled him to assume. The southern part fell to Heber; Leinster and Connaught to Heremon, who fixed his residence at Teamor, now called Tarah, in Meath. A war soon broke out between the brothers, which was terminated by the total defeat of Heber, the aggressor, who was killed in a battle fought at Geisiol, or Geashil, in the King's County. But his death did not put an end to the domestic dissensions of the family. A few years after, Heremon put his remaining brother to death, and thus obtained the sole dominion, which he held for thirteen years, till his death. His time was chiefly employed in repelling invasions of the Britons and of the Picts. The government then continued through a race of twenty kings of the same family, of whom nothing worthy of mention is recorded; the annals of the period containing merely the intestine dissensions of the chiefs of the several branches, and their wars with the Britons and Picts, until the crown descended to Ollav Fola, of the family of Ir, one of the sons of Milesius who had perished on the first landing in Ireland. During his reign, which commenced about 900 years before Christ, the Fez, or triennial meeting of the subordinate chieftains, priests, historiographers, and bards, was instituted at Teamor, or Tarah, in which, besides the regulation of all matters affecting the government and the enacting of laws, a minute investigation was entered into of the national monuments and records. Whatever was then deemed genuine and authentic, was inserted in a volume called the Psalter of Tarah. This legislator closed a reign of forty years, spent with benefit to his subjects and honour to himself, by a natural death, a circumstance very unusual in the annals of those times, and left the undisputed succession to his son, who enjoyed it for seventeen years, and also had the unusual good fortune to die in the same manner. The annals of the succeeding monarchs, for the space of 260 years, present nothing but a reiteration of war and mutual destruction, to such an extent, that out of thirty-one kings, who held the reins of government during that period, all but three are recorded to have fallen in battle, or by a violent death. The only occurrences worthy of notice that can be gleaned from the history of this barren period, are, the erection of a mint, the formation of a standing army by the allowance of a fixed pay to the soldiery, and the invention of the small boats, formed of wicker-work and covered with hides, now called corraghs.

Kimbath, who ascended the throne 460 years before Christ, has obtained an honourable celebrity by his efforts to revive and improve the institutions of Ollav Fola. He formed a national police, and regulated the artificers and tradesmen, whom he placed under the jurisdiction of a council of sixty of the nobles and learned men, without whose license no person was permitted to practise any mechanic art. The foundation of the royal palace of Eamania, near Armagh, is attributed by some writers to him; whilst others give the credit of it to his widow, who succeeded him, and reigned seven years, when she was cut off by her successor, who in his turn fell by the hand of Hugony the Great, in revenge for the death of his foster mother. This last-named monarch, with whom the line of Heremon would have terminated had he died without issue, was married to the daughter of a king of France, and kept possession of the crown during a vigorous and active reign of thirty years. He obliged the Picts to pay tribute, and extended his dominion over the Western Isles. He also abolished the pentarchical form of government, dividing the country into twenty-five provinces, over each of which he placed one of his twenty-five sons, and causing the public revenues to be collected according to this arrangement. But neither his virtues nor his abilities were sufficient to save him from the usual fate of Irish monarchs, nor to prevent the recurrence of acts of slaughter amongst his posterity. He was slain, after a reign of thirty years, by his own brother, who fell by the hand of one of Hugony's sons, who in his turn perished by the treachery of his only brother. Amongst the successors of Hugony, Eochy, surnamed Feileagh, or the Melancholy, has made his reign memorable by founding the royal seat of Croghan, in Connaught. It is also celebrated as being the era of the red-branch knights of Ulster, who were said to have had a residence at the palace of Eamania. His successor Eochy introduced the custom of burying in graves instead of burning. Conary More, who reigned for thirty years according to some writers, and sixty according to others, is famous for having enjoyed the longest, happiest, and most tranquil reign in Irish history. Such periods are not those which furnish most materials for the annalist. Of the particulars of his life, though so highly celebrated, little is recorded. He was killed in battle by the king of Wales, though other accounts state that he was treacherously burned in his own palace of Teamor, which also became a prey to the flames. In the reign of Crimthan, one of his successors, who had married the daughter of a Pictish chieftain, the Irish were the auxiliaries of the Picts against the Romans. The information of the leader of a rival faction to this prince is said to have induced Agricola to entertain the idea of conquering the island with a single legion and some auxiliaries. Whatever might have been the result of such an invasion under a general of acknowledged military talents, it is certain that the Roman power in Britain declined so rapidly from this time, that the Irish made frequent irruptions into the Roman province, and returned to their own country loaded with spoil. Feredach, one of the successors of Crimthan, owes his title of the Just to his chief councillor Moran, whose rigid impartiality in the dispensation of justice is recorded, in the figurative language of the bards, under the allegory of a collar, invented and handed down by him to his successors in office, which had the supernatural effect of pressing upon the neck of the wearer in case his decision deviated from the strict rule of equity, so as to strangle him if he persevered in his iniquity. Feredach was killed after an unsettled reign of seven years, by an insurrection of the peasantry, to whom the name of Attacots was given; a name which afterwards was carried into North Britain, where, though at first applied to disturbers of the public peace, it ultimately became the distinguishing title of a tribe inhabiting the country adjoining the Roman wall. After a period of civil commotion, Tuathal, upon attaining the sovereign power, exerted himself to restore the ancient constitution of Ollav Fola, and the pentarchical division of the country. To him is attributed the appropriation of the central province of Meath, as a demesne or mensal land for the supreme monarch. Here he restored the royal residence, and founded an edifice for the sacred fire, to which the Druids and priests were to have recourse on the last day of October, to perform a solemn sacrifice, and to supply fire to all the people, who were bound to extinguish their usual fires at that time, and to relight them from this hallowed source. He built similar palaces and temples at Uisneacht in Connaught, at Flaodha in Munster, and at Tailtean in Ulster, where there was a fair, to which parents brought their grown-up children and contracted them in marriage. He also was the originator of the fine afterwards known by the name of the Boromé, or Leinster tribute, imposed upon the king of that province for having caused the death of two daughters of Tuathal, whom he inveigled away under a treacherous promise of marriage. This monarch died in battle. The reign of Conn Keadcahagh, or Conn of the Hundred Battles, is best known by the division of Ireland which he was compelled to make with Mogha Nuod, king of Munster. The line of demarcation was fixed by a rampart and fosse, extending across Ireland from Dublin to Galway, the country to the south of which was called Leagh Mogha, or Mogha's share, that to the north Leagh Cuin, or Conn's share; names still familiar amongst the Irish. Cormac, the grandson of Conn of the Hundred Battles, signalized himself by his efforts to restore the ancient regulations of the monarchy; but having lost an eye in suppressing a rebellion excited by one of his own family, and being thus excluded from the throne through the prevalence of a prejudice which forbade a mutilated person to continue monarch, he closed his life in retirement, during which he drew up a treatise, yet extant, called the Book of Advice to Kings; a work extolled by the native writers as worthy to be written in letters of gold, a perfect standard of policy to all ages. In his reign flourished the celebrated Irish militia, known by the name of Fiana Erion, and commanded by Fein M'Cooil, commonly called Fingal. It was a military association, into which admission was attainable only by convincing testimonies of great strength, activity, and intelligence; besides which, an engagement was required on the part of the newly-admitted member to choose a wife solely for her merits, never to ill-treat a woman, and not to turn his back upon an enemy, even though nine times as numerous as the body to which he belonged. The regular number of this force was said to be nine thousand men, divided into three battalions. After a variety of exploits, which have furnished materials to much of the legendary romance of the time, the body was annihilated during the succeeding reign, at the battle of Gabra or Gawra, in Meath, where Oscar, the son of Ossian the poet, fell. Passing over a series of several kings known only by name, Nial of the Nine Hostages signalized himself by his military expeditions in Scotland, England, and France. His career of conquest was cut short in the last-named country, where he died of the wound of an arrow treacherously discharged against him on the banks of the Loire. His immediate successor, Dahy, met with an untimely fate in the same country by lightning. He was the last pagan king of Ireland. In the third year of Logary, or

Lae-ra, who succeeded Dahy, Palladius arrived in Ireland, being sent on a mission thither by Pope Celestine for the conversion of the natives. He was not, however, the first who had been thus employed. The names of St Albe, Declan, Iber, and Kirian, are quoted as his predecessors in the pious work. But their labours were confined to particular districts, nor does it appear that they acted under the authority of the see of Rome. Either through ignorance of the language, or want of spirit to withstand the ferocious opposition of his pagan adversaries, Palladius was compelled, after having founded three churches, to relinquish the design, and to quit the country, in order to save his own life and those of his followers; but he was prevented by death from returning to Rome to give an account of his mission. The completion of the work so inauspiciously commenced was reserved for St Patrick, whose success has acquired him the title of the apostle of Ireland. He was a native of North Britain. When sixteen years old he was brought prisoner to Ireland by Nial of the Nine Hostages, during one of his foreign expeditions, and spent seven years in slavery in the country, where his employment was the herding of swine. The law of bondage at that time extended no longer than the seventh year, at the expiration of which time he returned to his native country; and, after having studied under his uncle, the Bishop of Tours, he found his way to Rome, where he was selected by the pope to renew the attempt which had already failed; an undertaking for which his knowledge of the language, acquired during his captivity, peculiarly qualified him. To Ireland, therefore, he proceeded with twenty disciples or assistants, which number was increased to thirty-four in England, where he touched during his voyage. His first reception on his landing at Wicklow was very discouraging. The report of his arrival had already reached the Pagan prince who had expelled his predecessor. The same spirit of hostility was directed against the new comer, and Patrick and his company were assailed and forced to take refuge on board their ships. But, though discouraged, he was not disheartened. Instead of relinquishing his purpose, he proceeded to the island afterwards named Holm-patrick, where, having refreshed himself by a short leisure, he proceeded to Ulster, and preached before the chieftain of the district so forcibly as to convert him and his family, and to obtain license to found a church there. In the second year of his mission he presented himself before the Fez, or council at Tarah, where he proved equally successful; Logary the king declaring himself a convert, and many of his subjects following his example. Nor does it appear that the subsequent progress of the apostle was checked by any untoward circumstance. The remainder of his life, which was protracted to an unusual length, was spent in traversing the country, spreading around a knowledge of the Christian doctrine, gaining over converts, and founding churches and monasteries. The chief of his religious foundations was at Armagh, which soon became a school of theology, so famous that students flocked to it from all quarters in such numbers, that at one time it was said to have communicated instruction to seven thousand students. The exertions of Patrick were not wholly confined to the preaching of the gospel. He gave his advice and assistance in the reformation of the government. At his suggestion, Logary summoned an assembly of the princes, historians, and antiquaries, to revise the records and chronicles of the country; and their amendments were deposited in the public archives, under the name of "The Great Antiquity." Fragments of copies taken from this work were to be met with for many centuries afterwards, under the names of the Book of Armagh, the Psalter of Cashel, the Book of Glandaloch, the Leabhar Gabala, and others, from which subsequent writers have derived much of their information respecting the ancient history of the country. Patrick did not retain the government of the bishopric erected by himself in Armagh; but having appointed Binen or Benignus his successor in the see, and having made a visit to Rome, he spent the remainder of his life chiefly at Saul, near Downpatrick, where he had founded a monastery, in which he closed a career of active and successful labours, in the hundred and twentieth year of his age, and was buried in the neighbouring abbey of Downpatrick.

Although the exertions of St Patrick produced an effect so great upon the public mind, that, for many years after, the founding of religious institutions, and the lives and deaths of the ecclesiastics engaged in maintaining and extending the new faith, formed the chief subjects of history, it does not appear that the change of religion produced the beneficial alterations that might have been hoped for from it on the political aspect of affairs. The brief notices of the civil occurrences continue to exhibit little more than a reiteration of the turbulence, crime, and desolation, that had marked the era of paganism. The only event of importance that diversifies the tissue of domestic and foreign warfare which forms the subject of the annals of those days, occurred during the reign of Hugh, the son of Ainmireagh, in which an assemblage was convened at Drumkeath, in Derry, for the express purpose of curbing the license of the bards, now become intolerable. The privileges annexed of old to this order, whose properties as well as persons were inviolable in all civil commotions, whose lands were freed from tribute, and whose houses were respected as sanctuaries, had rendered the numbers of the profession so great, and entailed such a burden on the state for their support, that they were several times before about to be banished from the country. At the assembly now held, they found a zealous and useful friend in the celebrated Columbkill, who left his monastery of Iona to be present here, and prevailed so far as to procure a mitigation of their treatment, by changing the decree for their banishment into one for the diminution of their numbers. It was therefore resolved, that in future the king of Ireland, each provincial sovereign, and the lord of every subordinate territory, was to maintain a bard to preserve the genealogies and record the acts of the respective families; and that a suitable salary was to be allowed him, in return for which he was also to instruct the youth in history, poetry, and antiquities. The whole body was placed under the control of an arch-poet, in whom was vested the power of admitting qualified persons. Thus restrained as to numbers and means of acquiring wealth, their properties were as hitherto exempted from taxation, and their persons privileged. Yet, during this gloomy period, in which the internal state of the country exhibits so little to cheer the inquirer, it became celebrated throughout Christendom, on account of the piety and learning of the inmates of its religious establishments. In the fifth century Sedulius made himself known as a poet, an orator, and a divine, and spread a knowledge of his acquirements, and the fame of the country in which he had imbibed them, through France, Italy, and the western regions of Asia. Columbkill, already transiently noticed as the founder of the monastery of Iona or Hy, the burial-place of the Scottish kings, adorned the sixth century. So also did Congall, the founder of the monastery of Bangor, famed for the multitude of religious men whom its learning and the strictness of its rules led to it. In the seventh century flourished Columba, the founder of several monastic institutions in France and Italy; Aidàn, to whom the conversion of the Northumbrians is attributed; Finan, who followed him in the same field of missionary labour; Argobast, who preached in Alsace, and was thence raised to the see of Strasburg; Adamnanus, who visited the court of Alfred, king of Northumberland; and Cuthbert, the son of one of the petty kings of Ireland, who, after having been prevailed on with much difficulty to take charge of the bishopric of Holy Island, in the same part of England, resigned it for a life of studious retirement in the Isle of Farn, where he closed his life. In the eighth century lived Sedulius the younger, who assisted at a council held at Rome by Gregory II., and was afterwards a bishop in Spain; also Vergilius, a philosopher as well as a divine, as appears by a treatise of his on the Antipodes, written against the then received opinion of the shape of the earth, which he proved to be a globe, and not a plain surrounded by the heavens at its verge. He spent some time in France at the court of King Pepin, by whom he was highly esteemed.

The state of Ireland was now destined to suffer from another element of convulsion. About the commencement of the ninth century, the Danes began to extend to it their predatory ravages. Their first attacks were trifling and occasional, more of the nature of piratical incursions than preconcerted invasion. But in proportion as the success of their first assaults rendered them more daring, and their more extended knowledge of the country made them better acquainted with its fertility, their bands became more numerous, and better prepared for continued hostilities; whilst at the same time the unsettled state of the country, caused by the intestine wars of the native princes, carried on either for the purpose of attaining the supremacy, or for exacting tribute from their inferiors, prevented that combination of defence which alone could ensure success against the foreign enemy. In the middle of the same century, Turgesius, king of Norway, had virtually rendered himself monarch over the greater part of the island. He maintained himself in it with all the cruelty and arrogance of an usurper. Danes were placed in all the subordinate kingdoms. Every district had a Danish officer placed over it, and even every house was required to maintain a Danish soldier. The use of arms was prohibited to the Irish. A tribute of an ounce of gold was exacted from every householder, the non-payment of which was punished by the mutilation of the nose, whence the tribute was known by the name of the nose-tax; and, to complete the climax of degrading submission, the bridal favours of new-married virgins were exacted by the Danish chief of the territory, and were sometimes commuted, at his caprice, for a sum of money. The country had groaned for thirteen years under this complication of insult and injury, until it was at length roused to shake off the degrading yoke. Turgesius had erected a rath for his residence in the neighbourhood of Tarah, where lived Malachy, who still retained the title of king among the Irish. Turgesius claimed his daughter. Malachy, conscious of his inability to resist the demand openly, yet unwilling to sacrifice his only child without an effort, sent along with her a number of young men disguised as her female attendants, who fell upon the Danes in the rath, slaughtered them, seized Turgesius, and handed him over bound to Malachy, who had advanced with a band of armed men to their aid. The captivity of the tyrant was the signal for a general insurrection of the Irish, by which the Danes were forced either to fly aboard their shipping, or to take refuge in the maritime towns that acknowledged their authority. Turgesius, after being kept some time in prison, was drowned in Lough Innel. On the expulsion of the Danes, the country reverted to its former state of internal dissension. Cormac M'Cuillenan, king of Munster and bishop of Cashel, an union of civil and spiritual jurisdiction then not uncommon, claimed a tribute from the king of Leinster, which, on refusal of payment, he proceeded to enforce by the power of his arms. But on entering his adversary's territory, he found him strengthened by the support of the king of Ireland. The unexpected intelligence threw such a damp upon the spirits of his troops, that many deserted him before the battle: those who stood firm were soon routed, and Cormac himself was killed by a fall from his horse, whilst endeavouring to escape amongst the fugitives. This king is best known in history as the compiler of a book of annals, called the Psalter of Cashel, from which succeeding writers derived much information. It has been many years lost.

The internal dissensions of the country encouraged the Danes to make another effort for subjugating the island. A large force landed in Leinster, under the command of Setrick, said by some writers to have been a son of Turgesius, by whom Dublin was taken, and the possession of it secured by a signal victory obtained over the combined forces of the Irish, in which Nial, king of Ireland, and many of his generals, fell. The distractions of the country, thus augmented by the presence of a foreign enemy, obtained a temporary intermission by the accession of Brian Boree to the sovereignty. This prince, the great hero of the Irish, was brother to the king of Munster, on whose death he succeeded to the throne of that province, from which he not only expelled the Danes, who had made a settlement in Limerick, but extended his dominion over the whole southern division of Ireland. The brilliancy of his achievements against the common enemy induced the rest of the subordinate chieftains to unite in a confederacy for deposing Malachy, the reigning monarch, and raising Brian into his place. The object was effected with little difficulty, and, what was more unusual in the revolutions of the country, with no bloodshed. Malachy was of a mild and undecided character. After a feeble effort to revive the spirit of loyalty among the subordinate princes of the northern division, to the chief of whom, O'Neill, he offered a large portion of his dominions, he resigned the crown without a struggle. The new monarch was publicly proclaimed and inaugurated at Tarah. After receiving the submissions of the kings of Ulster and Connaught, and reducing some refractory chieftains who disputed his authority, he directed the combined energies of all the states against the Danes, whom he expelled from the island, with the exception of such as consented to embrace Christianity. These he located in the great seaports of Dublin, Wexford, Waterford, Limerick, and Cork. Having thus removed the obstacles arising from a foreign enemy, he directed his attention to the general civilization of the kingdom, by founding or restoring the places of worship and seminaries of education, building bridges, opening passes, erecting fortresses, and fitting out a fleet to oppose the Danes on their own element, before they could effect a landing. In the accomplishing of these objects, he spent the latter part of a long and glorious reign. But its termination was marked by a circumstance that undid all his labours. The subordinate king of Leinster, irritated at an insult offered to him in the court of Brian, made overtures to the king of Denmark for a union to expel him from the throne. These were gladly accepted. A large fleet was sent from Denmark, which landed a body of troops near Dublin, where they were joined by those of the king of Leinster. Brian was not negligent in discovering, or tardy in adopting measures to resist, this new combination. At the head of a numerous and well-appointed army, collected from all the other provinces, he marched to meet the enemy. The battle was fought on the plains of Clontarf. It was bloody and desperate, but decisive; the Danes were utterly defeated, and forced to fly to their ships. The Leinster men, abandoned by their foreign friends, were cut to pieces without mercy. The exultation of triumph would have been as unmixed as the victory was glorious, had it not been clouded by the death of the monarch, who, though too far advanced in years to take part in the engagement, led the army to the field, and was killed in his tent, whither he had remained during the conflict, by a party of straggling Danes, as they

History.

were flying. His eldest son Mortogh fell in the battle. Malachy, the deposed monarch, seized the opportunity of reviving his claim to the vacant throne. His conduct during the late crisis had been more than dubious. He had made a show of assisting the Irish with the forces of Meath, which province he had been allowed to retain, but, on the commencement of the battle, withdrew his men to a neighbouring eminence, where he continued an inactive spectator of the struggle. His claim was acquiesced in. But his resumption of the reins of authority proved only the signal for the renewal of those scenes of turbulence and anarchy which the commanding talents of his predecessor had kept under control. The apprehensions of subjugation to a foreign power were indeed removed. The victory of Clontarf discouraged any further effort of the Danes, whom alone the native rulers dreaded. These were left to carry on undisturbed their schemes of self-aggrandizement and mutual contention. The only event to diversify the gloomy monotony of incessant civil discord, was a synod of the clergy at Kells, held in 1152, under Cardinal Papiron, the pope's legate. Heretofore the connection of the Irish church with the see of Rome had been very slight, and altogether voluntary. It was governed by the two Archbishops of Armagh and Cashel, and a number of bishops, whose system of control was regulated by domestic synods. At the assemblage now spoken of, the supremacy of the see of Rome was acknowledged, and four palls were given to the Archbishops of Armagh, Cashel, Dublin, and Tuam.

Things continued in this state till the time of Roderic Connor, whose reign forms the commencement of a new era, which overthrew all the ancient forms and constitutions of government, and gave to the tide of political events a new turn, by which they have been influenced to the present time. Notwithstanding the proximity of England to Ireland, there had hitherto been but little intercourse between the two countries. Wales, then an independent state, interposed between them. The Saxons were not a people of commercial or adventuring enterprise; and, even after the final consolidation of England into an established monarchy under the Normans, the views of the monarchs of this line, whether for extension of territory or for commerce, were directed towards the states of the Continent, whence they had derived their parentage. We read indeed of an invasion, and even a subjugation of part of Ireland, by Edgar, king of the Northumbrians. If such occurred, it has left behind it few or no historical traces. The episcopal see of Dublin acknowledged the supremacy of that of Canterbury, from which it received its canons and rights of ordination. The Danish character of the city, which, until after the English invasion, was always considered as a subordinate seaport, accounts sufficiently for this peculiarity; and that the connection between the two kingdoms had nothing in it savouring of subjection on the part of Ireland at the time now about to be entered upon, appears from the fact, that at the synod of Armagh, assembled in 1170, to inquire into the cause of the arrival of strangers from England for the purpose of conquest, the impending calamity was imputed to the sins of the people, and more especially to the practice of buying English children, and making them slaves. Giraldus Cambrensis, in stating the fact, adds, " that the English, by a common vice of their country, had a custom to sell their children and kinsfolk into Ireland, although not driven to it by extreme poverty."

Dermot M'Murrough, king of Leinster, had incurred the hatred of his own subjects, and of the other princes, by his tyranny. His breach of the laws of hospitality in carrying off the wife of O'Ruark, king of Breffney, gave particular offence to Roderic, by whom he was consequently driven from his dominions. In his distress he had recourse to Henry II. of England, under whom he offered to hold his crown as a tributary, if restored by that monarch's exertions. The offer was very grateful to Henry. He had long before turned his thoughts to the acquisition of Ireland. As early as the year 1154, he had procured a bull from Adrian, who owed his elevation to the papacy to Henry's influence, conferring on him the sovereignty of the island, in order to its civilization, upon payment of the tribute of Peter's pence to the court of Rome. But his domestic difficulties and continental engagements had hitherto obliged him to postpone any active measures to accomplish his object. He was now in Guienne, embarrassed by rebellion amongst his French subjects, and by his disputes with the papal see, and therefore was forced to confine himself to general expressions of assent, confirmed by a permission to all his English subjects to assist in the restoration of his new ally. Supported by this authority, Dermot turned homewards, and, after vainly attempting to engage adventurers in Bristol, he at last formed a treaty with Richard, earl of Pembroke, and Strigul, better known by the name of Strongbow, a Welsh baron, who, having impaired his patrimony, was easily engaged to take part in a desperate enterprise, on the uncertain expectation of inheriting the kingdom of Leinster after Dermot's death, by a marriage with his only daughter, which was to be the reward of his exertions if successful. Through Strongbow's influence, he also engaged the assistance of Robert Fitzstephens, constable of Abertivi, and of Maurice Fitzgerald, a Welsh chieftain. Having secured these auxiliaries, Dermot returned to Ireland, where he lived concealed in the monastery of Ferns, the confidence of whose inmates he had gained by liberal donations to their house, until the arrival of his new friends warranted him in asserting his former station.

Fitzstephens was the first to fulfil his engagement. He landed at the headland of Bag-and-Bon, in the estuary of the Bannow, with a following of but thirty knights, fifty gentlemen, and three hundred archers. Small as the number was, their discipline and superiority in military equipment justified Dermot in throwing off the veil on their appearance. The first movement of the combined force was upon the town of Wexford, a Danish dependency of the crown of Leinster, which surrendered on the first appearance of the enemy, and was, with the two adjoining cantrids of Forth and Bargie, given to Fitzstephens by Dermot, as a foretaste of what was to be hoped for in his service. The next movement was against the king of Ossory, in the Queen's County, who, after a gallant struggle, was also forced to acknowledge the superiority of the Norman mode of warfare. After a hard-fought contest of three days, the passes of his borders were forced, and himself compelled to fly. The news of these successes soon compelled Roderic to take the most decisive measures. At the head of an army collected from all the subordinate provinces, he advanced to drive the rebel king and his foreign auxiliaries into the sea; but the interference of the clergy prevented the appeal to arms. A treaty was concluded, by which Dermot was restored to his former rank, on condition of dismissing his foreign forces, and paying a fine for his outrage against O'Ruark. His son was delivered to Roderic as a hostage, along with others, for the fulfilment of the terms.

The arrival of Maurice Fitzgerald, who landed at Wexford with ten knights, thirty gentlemen, and an hundred archers, gave a new turn to affairs. Fitzstephens, who was then engaged in erecting a fortified post at Carrig, which commanded a pass on the Slaney, near Wexford, resolved to maintain his position. Little influence was necessary to induce Dermot to aid an effort as profitable in expectation as perfidious in act. Encouraged by the hope that this new supply would be the prelude to the influx of fresh bands of well-trained warriors, he indulged in the prospect of gratifying his revenge on the causes of his degradation, and even of seating himself on the throne of supreme sovereignty, through the powerful aid of his English allies. For this purpose, after having reduced the city of Dublin to submission by the devastation of the neighbouring district of Fingal, thus establishing his rule over the whole of his former dominions, he sent to urge Strongbow to hasten his arrival.

This nobleman, not satisfied with the general permission already given by Henry, went to that prince, then in Normandy, and having obtained a vague and equivocal assent, prepared for the vigorous prosecution of his enterprise. He first sent over Raymond le Gros, with a detachment of ten knights and seventy archers; who, landing near Waterford, defeated a body of three thousand Irish, collected from the neighbouring country on the spur of the moment, and maintained his position in an intrenched camp until supported by Strongbow himself, who brought to his relief a body of two hundred horse and upwards of a thousand archers. He then, aided by the junction with Dermot, who had hastened to the place, made himself master of Waterford, and thence proceeded to Dublin, which was taken by assault. Roderic, alarmed at the successes of the English, after having called in vain on Dermot to abide by the late treaty, and having, according to some accounts, beheaded that king's son, in consequence of his father's refusal to fulfil the terms of it, collected another army to oppose the invaders. Dermot's death at this juncture gave a new character to the contest. Strongbow, by his marriage with that prince's only daughter, had succeeded to his royal rights; but being unsupported by any of the Irish chieftains, who viewed with apprehension and envy this intrusion of a stranger, he found himself cooped up in the city of Dublin, with his small band of Englishmen, to stand the brunt of the entire Irish army, with which Roderic had invested the city. But he was delivered from this critical situation by one of those exertions by which a vigorous mind surmounts difficulties. He had been reduced to the necessity of proposing a capitulation. The only terms offered him were the immediate evacuation of the country. Such a surrender of all their brilliant prospects was to these daring adventurers a prospect worse than death. Mito de Cogan, by whose valour in leading the assault the city had been taken, now proposed a sally. His advice was followed. Strongbow, at the head of a select body of ninety knights, attacked the Irish camp. The assault was so sudden and unexpected, that Roderic had scarcely time to escape from the bath, where he was then refreshing himself. The panic spread through all parts; and this great army was dissipated almost without a blow. The English followed up their good fortune by marching to Wexford to relieve Fitzstephens, who was blocked up by the Irish in his castle of Carrig. In the passage thither, the army had to force its way through the passes of Idrone, where O'Ryan, the dynast of the territory, disputed the ground with it successfully, until his death turned the fate of the day. It is said that the English were so severely pressed in the engagement, that Strongbow's son, a lad rising into manhood, fled from the fight, for which he was hewn in two by his indignant father. A mutilated figure on a small monument placed by the side of Strongbow's tomb in Christ Church, Dublin, is still adduced as evidence of the truth of this extraordinary event.

The successes of Strongbow excited the jealousy of Henry, who began to apprehend in them, not the enriching of a subject, whence the monarch might derive honour, but the aggrandizement of a rival in power. He forbade any of his subjects going to the assistance of the English in Ireland, and commanded the immediate return of all those already there. He was, however, appeased by the appearance of Strongbow himself, who surrendered all his possessions in Ireland to the king, to be holden at his good pleasure. He was restored to favour, and appointed seneschal of this new lordship, with the exception of Dublin and the other fortified cities, which the king retained in his own hands. Henry soon afterwards went over to Ireland with a train of 500 knights, and a large body of soldiers. Landing at Waterford, he proceeded without molestation to Dublin, where he received the homage of a numerous assemblage of the native chieftains, whom he entertained in a pavilion hastily constructed of wicker-work without the walls, as the city then contained no building suitable for their accommodation. He also held a great council or parliament at Lismore, in which the English laws were received and sworn to. At the same time a synod of the clergy at Cashel adopted the rules of doctrine and discipline of the English church for their future regulation. After spending the Christmas in Dublin, and dividing the districts that acknowledged his authority among the chief leaders of the adventurers by whose valour they had been acquired, he returned to England early in spring, to allay the commotions which threatened to break out there.

His absence gave rise to dissensions amongst the English leaders, which led to revolt amongst the natives, who had so lately submitted. To aid the efforts of the Irish, Roderic made another attempt to regain his lost dominions, and to expel the strangers. He invaded Meath, which had been given by Henry to an English baron of the name of De Lacy, with such fury, that Raymond le Gros, the favourite general of the English, who was then celebrating his marriage with the sister of Strongbow, was forced to quit Wexford the morning after his nuptials, in order to make head against the Irish. But they, content with the devastation committed in Meath, had already retired across the Shannon, and Raymond turned his arms against Limerick, which city he took by storm with little difficulty. Roderic, convinced of his inability to cope with success against the superior power of England, sent deputies to the king, proposing to do homage, and pay a stipulated tribute, in return for which he was to hold the kingdom of Connaught, and all his other lands and sovereignties, as fully, in other respects, as before the arrival of the English.

On the death of Strongbow, who died and was buried in Dublin, leaving behind him an only daughter, the heiress of his princely domains, the government of Ireland was committed to William Fitz-Andelm, a nobleman allied to Henry by blood; but the complaints arising from his indolent and corrupt administration became at length too loud to remain unnoticed. He was therefore removed, and John, the king's favourite son, was appointed lord of Ireland, at the early age of twelve years. On his arrival at Waterford, at the head of a train of young and arrogant noblemen, the native chieftains hastened to pay their respects and do him homage; but when they approached to testify their allegiance according to the custom of the country, by saluting him with the lip, the prince's English attendants repelled them with insolence, plucked them by their beards, and treated them with every mark of studied indignity. The high-minded natives quitted the court, and their cause was espoused by all who heard their tale. The alarm of war was spread throughout every part of the country. The castles already built by the English on their newly-acquired territories in Meath were stormed and razed, some of their owners killed, and others driven from their settlements. John was recalled, and the government intrusted to De

Lacy, who was soon afterwards assassinated by one of the natives whilst superintending the erection of a fortress which he was building, sacrilegiously, according to the opinion of the times, on the ruins of an abbey dedicated to Columbkill at Durrow. He was succeeded in the government by De Courcy, a nobleman celebrated for his gigantic size and prowess. He had been given such parts of Ulster as he could conquer; and having established his head-quarters at Down, he maintained himself there for some time in a kind of subordinate sovereignty, against all the efforts of the neighbouring princes, and even made an attempt to extend his conquests into Connaught, in doing which, though he failed in the main object of his ambition, he established his power in the neighbourhood of Armagh. The death of Henry II. made no change in the government of Ireland. Richard, intent on his schemes of foreign conquest, permitted John to retain the title and authority conferred on him by his father. The only event which varied the scene of intestine commotion in Ireland during this reign, was the death of Roderic, the last sovereign of all Ireland. The latter years of his life were embittered, in addition to the loss of his independence, by the rebellious conduct of his own sons, which at last compelled him to seek, in the retirement of monastic seclusion, the tranquillity he had vainly sought for on a throne. He died in the monastery of Cong, in 1198, in extreme old age.

John, in the early part of his reign, paid little attention to the affairs of Ireland, which was now much distracted by the feuds carried on between De Lacy, son of him who had been killed at Durrow, and De Courcy. In this struggle the artful management of the former gained him the advantage over De Courcy's blunt and boisterous ferocity. He accused him of having imputed to John the murder of his nephew Arthur, in consequence of which, De Courcy was summoned to the court in London; and when he treated the mandate with contempt, he was treacherously seized by his enemy De Lacy, while performing a religious penance unarmed in the church of Down, and sent prisoner to England, where he was long kept in confinement. A proceeding as unworthy as this which exposed De Courcy to the royal indignation, brought John a second time to Ireland. The lady of William de Braosa, who had received a large grant of land in Thomond, or North Munster, on being required to send her children to the English court as hostages for her husband's allegiance, refused to obey; alleging as a reason, that she would not intrust her children to the care of the murderer of his own nephew. The insult was unpardonable, and John went over in person to avenge it. Upon his arrival in Dublin, upwards of twenty chieftains attended to do homage; but he performed no military act worthy of notice. The unfortunate De Braosa was forced to fly to France, leaving his wife and family behind, who were seized by the tyrant and sent to England, where they died of the severity of their treatment in prison. During his short stay, John paid much attention to the internal management of the country. He ordained that the laws of England should be introduced, with all their judicial forms, a copy of them being left under his great seal, in the exchequer of Dublin. He also divided the districts which acknowledged his authority, and which were afterwards distinguished by the name of the Pale, into the twelve counties of Dublin, Meath, Kildare, Louth, Carlow, Kilkenny, Wexford, Waterford, Cork, Kerry, Tipperary, and Limerick. In the remainder, which comprehended two thirds of the island, the king's supremacy was merely nominal. Connaught, which Roderic in his treaty with Henry had specially reserved to himself, after suffering dreadfully by the contentions of that monarch's sons, and by the irruptions of the English leaders, who endeavoured, by their interference in these family quarrels, to obtain some footing in it for themselves, fell ultimately into the hands of Cathal, surnamed Croove-derg, or the Bloody-handed. But the influence of the De Burghos, a branch of the family of Fitz-Andelm, proved too powerful for him. After many a desperate struggle with the intruders, in which his undisciplined valour enabled him to cope at times successfully with the well-marshalled followers of the English chieftain, he was compelled to surrender two parts of the country to the king of England, in order to secure to himself the peaceable possession of the remainder; at the same time acknowledging himself a vassal, and binding himself to a yearly tribute of an hundred merks. On the departure of John, who continued but a short time in the country, the government was intrusted to John de Grey, bishop of Norwich, who conducted it with prudence and vigour; and afterwards by Henry de Loundres, archbishop of Dublin, the most remarkable act of whose administration was the erection of a castle in Dublin, now the acknowledged capital of the English territory.

Immediately after the accession of Henry III. the Irish transmitted to England a list of the encroachments made on their rights in the preceding reign, with a petition to be taken under the royal protection. Henry sent them in answer a copy of the Magna Charta, whereby they were to be placed on the same footing as English subjects. This charter was confirmed by others of a similar tendency, transmitted by the same monarch. He also gave O'Brien, king of Thomond, a grant of that territory, to be held by English law, in lieu of the Irish tenure by which he had hitherto possessed it. The change was considered of such value as to be worth the payment of a thousand merks, and an annual sum of an hundred and thirty. But the king's promise of impartial protection to the Irish was grossly violated in the instance of Cathal Croove-derg, who was now deprived of the third part of his kingdom that had been allowed to remain with him by John, this portion being granted, together with all the rest of Connaught, to Richard de Burgho. Cathal died soon after this unjust deprivation of his property. His subjects, assisted by O'Neill, prince of Tyrowen, placed his brother Tirlogh on the throne; but he was removed by the lord-deputy, and Aedh, a son of Cathal, substituted in his place. Aedh being shortly afterwards killed in a skirmish, the lord-deputy again removed Tirlogh, whom the people of Connaught had reinstated, and placed Feidlim, another son of Cathal, upon the throne. But a title held under a tenure so precarious and degrading could not be satisfactory. Feidlim, therefore, crossed over to England, and threw himself on the protection of the king, by whom he received a special assurance of security in the possession of his territories, which enabled him to retain them unmolested till his death.

Towards the conclusion of his reign Henry made a grant of Ireland to his eldest son Edward; with a proviso, however, that it was to be always connected with and dependent upon the crown of England. The country derived no benefit from the arrangement. Edward was drawn away to pursue schemes of more brilliant promise in the Holy Land, and Ireland was suffered to continue under the management of subordinate officers. Its state was at this time truly miserable. In addition to the struggles of the Irish chieftains to regain their patrimonial rights of property and independence, the districts which acknowledged the English rule were torn to pieces by the hostilities of rival barons. To such a pitch did this state of anarchy increase, that in a contest between the De Burghos and the Fitzgeralds, the latter faction seized upon Richard de Rupella, the lord-justice of Ireland, and threw him, with several of his adherents, into prison, from which it required the authority of a parliament to liberate him.

The neglected state of the country during the reign of Edward I., whose attention was absorbed by the nearer and more pressing affairs of Scotland and Wales, increased the turbulence and audacity of the English barons. A dispute between Sir William de Vesci, the lord-justice, who had married an heiress of the Pembroke family, and John Fitzthomas, one of the heads of the Fitzgeralds, was carried to such a pitch, that each accused the other of high treason; and the affair was brought before the king in person, to be decided by the law of duel. On the day appointed for the combat, Vesci was not forthcoming. He had fled to France. The king transferred his lands in Ireland to his accuser, which contributed considerably to the future aggrandizement of the Fitzgerald family. So grievously was the great body of the Irish pressed down by the arrogant tyranny of these feudal lords, that they offered the king six thousand merks for a charter from him to be governed by the laws of England. This reasonable request, which implied nothing more than the enforcing of the previous charters of John and Henry to the same effect, was neutralized by the opposition of the barons, whose oppressions it was meant to curb. A second application of a similar nature during this reign met with a similar fate. The conduct of Edward to one of the lords-justices, De Ufford, whom he called over to explain why such quarrels were permitted during his administration, proves that the king was not over anxious to probe this malady to the bottom. De Ufford's defence of himself was, that "he deemed it expedient to suffer one knave to destroy another, to save expense to the king." Edward was satisfied with this evasive answer, and sent him back to his government. The wars of the barons were still tolerated; and the Irish, who wished for the protection of English law against their tyranny, were still forced to purchase it by special charters of denization, by the fees of which the officers of the court were enriched. These charters were mostly the consequence of intermarriages with some of the great English families.

The accession of Edward II. afforded a prospect of the restoration of the royal authority, and the suppression of the exorbitant power of the English barons. The king, compelled to part with his favourite Gaveston, sent him into Ireland as lord-lieutenant, as into a kind of honourable exile. On his arrival, Gaveston obtained some advantages over the Irish septs in the neighbourhood of Dublin; but, however flattering the appearances arising from this change of administration, they proved delusive. Edward, unable to endure longer his favourite's absence, recalled him, and the country fell back into the anarchical sway of the barons. The royal mandates were set at nought, and private wars carried on without restraint or control. Frightful as were the state and prospects of the country, a fresh ingredient of misery was now thrown in. Robert Bruce, king of Scotland, elated with the victory of Bannockburn, resolved on a measure which, if successful, would have added considerably to the security of his own kingdom, and to the weakening of his most formidable enemy. He proposed to detach Ireland from England, and to connect it with Scotland, either as an ally or a dependency. With this view, and also to give employment abroad to an ambitious and ardent relative, he proposed to his brother Edward the conquest of the country. The offer was accepted. The first attempt on the northern province failed, because the means were insufficient for the magnitude of the object. But Bruce was not to be discouraged by a single check. The attempt was soon afterwards renewed with enlarged resources. In the summer of 1315, Edward Bruce landed in the north of Ireland, at the head of six thousand men, where he was joined by numbers of the discontented Irish. De Burgho, earl of Ulster, aroused by the danger which threatened his possessions, aided by Feidlim, king of Connaught, marched to oppose the invader. Their combined force was defeated at Coleraine, and Bruce, following up his victory, reduced Carrickfergus; penetrated into Meath, where he defeated, at Kenlis or Kells, a second army sent to oppose him; advanced still further to Skerries, where he encountered and routed Sir Edmund Butler, the lord-justice; and returning to Dundalk, through want of provisions, was there crowned king of Ireland. His affairs were now singularly prosperous. His brother came to his assistance from Scotland, but was forced, through the scarcity of provisions, to return, leaving with him a part of his troops. Feidlim joined his party, and was followed by O'Brien of Thomond, and several lesser chieftains. The English barons now began to be sensible that the tenure of their possessions was at stake. They collected a numerous body of troops, which were sent, in the first instance, into Connaught, to put down Feidlim. A sanguinary battle ensued at Athenree, in which the Irish prince was slain, and with him terminated the last hope of the restoration of the monarchy of Ireland. Bruce, after refreshing his troops, marched to Dublin. To guard against his assaults, the citizens set fire to their suburbs, with such precipitation, that one of the churches was involved in the conflagration; and intrenching themselves within their walls, they presented such a face as deterred the besiegers from continuing the siege. Bruce therefore proceeded to Kildare, which he ravaged, and thence penetrated through the passes of Ossory into Munster, spreading havoc and desolation on all sides. Want of provisions, and the intelligence, on one hand, of another army having been collected against him, under the command of Roger Mortimer, sent from England as lord-justice, and on the other, of new supplies from home, led by his brother in person, induced him to retrace his steps towards Ulster. By forced marches he retreated unmolested into Meath. He was followed by the English, now under the command of Sir John Bermingham. Both armies met at Faugher, near Dundalk. The Scotch army was the more numerous, but it was much exhausted by fatigue and famine; the English were well equipped and armed, and in a high state of organization. It is said that Edward Bruce, on hearing that his brother was advancing, pressed on the engagement, in the hope of securing to himself the undivided honour of victory. The result was deserving of the arrogance which led to an act so ill advised and precipitate. After a sanguinary struggle, the Scottish army was totally defeated. The body of Bruce was found, after the engagement, in the midst of heaps of slain, lying under that of an English knight of the name of Maupas, who had pressed forward to the honour of being captor of the Scottish general. Robert Bruce, on hearing of the result, immediately returned home, and made no further attempt upon the country.

The expulsion of the Scotch gave little relief to the people, who still continued to groan under the feudal oppressions and interminable quarrels of their rulers. On the accession of Edward III. they addressed themselves again to the throne, in order to procure a general charter of admission to the rights of British subjects. The petition was favourably received; but being referred, like former applications of the same kind, to the Irish parliament, through the lord-justice, it was, like these, rejected. The Irish, disappointed in their hopes of good government, broke out into acts of insurrection. The king, unable to restore tranquillity by energetic measures, had recourse to others, the evil effects of which were long felt. The greater part of Leinster had been parcelled out into five palatinates, in favour of the five grand-daughters of Strongbow, on whom this princely inheritance had devolved in failure of male issue. Meath and Ulster had also been granted in like manner. The number of these exempt jurisdictions, in which the superior lord exercised most of the prerogatives of royalty, was now increased,

History.

by erecting the county of Desmond, or South Munster, into a palatinate in favour of Maurice Fitzthomas, a branch of the Fitzgerald family; and another was shortly after erected in Tipperary, for James Butler, created Earl of Ormond. In consequence of the great privileges bestowed on these noblemen, the king's authority was proportionally contracted, and a few powerful chieftains were enabled, under colour of asserting their rights, to overawe or control, by their combination, the wholesome exercise of the powers of the constitution, or to convulse the country to its centre, by their mutual contests for superiority. This ruinous system was carried still further. The chief governor, unable to collect men in numbers sufficient to cope with the insurgent Irish, applied for military aid to the Earl of Desmond. The request was readily acceded to, and ten thousand men were sent him; but as the deputy was deficient in the means of paying or feeding such a body, the troops were allowed to live on the country at free quarters, or, as it was then called, on coygne and livery, which consisted in the taking of man's meat, horse's meat, and money, of all the inhabitants, at the will and pleasure of the soldier, who had no other means of subsistence. This extortion was originally Irish, for they used to lay Bonaught, as they called it, upon the people, and never gave their soldiers any other pay. But under the English it was still more intolerable, as with them the oppression was not temporary or limited either in time or place, but, because there was everywhere a continual war, either offensive or defensive, and every lord of a country, and every marcher, made war and peace at his good pleasure, it became universal and perpetual, and was, indeed, the heaviest oppression that ever was inflicted on any kingdom, Christian or heathen.

The effects of this feeble policy proved the reverse of what its devisers may be supposed to have expected. Internal turbulence and discord increased. To heighten the confusion, William de Burgho, who united in his own person the government of the two palatinates of Meath and Ulster, and had also the greater part of Connaught, was assassinated at Carrickfergus by his own domestics. His only daughter was carried to England for protection. O'Neill of Tyrowen, to whose family the northern palatinate of De Burgho had formerly belonged, seized on the opportunity to recover by force a considerable portion of the inheritance of his forefathers. The estate in Connaught was also seized on by two of the younger branches of the De Burgho family, who, conscious of the illegality of their claim according to the rules of English law, renounced their allegiance, assumed the Irish name of M'William, distinguishing themselves from each other by the surnames of Eighter and Oughter, or the Hither and Further M'William; the former holding the lands in Galway, the latter those in Mayo, and both, conforming to the laws and tenures of the Irish, set the authority of the king's justice at defiance. But the act which tended most to destroy the English power, by unhinging the connection between the parent country and the colony that had sprung from it, was an order that all public officers whose property existed wholly in Ireland should be displaced, and their places supplied by persons born in England, and having lands in that country. This act gave rise to the distinction between the English by blood and the English by birth, causing those of the former class, through irritation at the insulting degradation by which they were deprived of their fair share of the honours and emoluments earned by the blood of their ancestors, not only to attach themselves to the native Irish by the ties of marriage and community of interests, but to exceed them in the intensity of hatred to the new intruders; and hence they were said to be more Irish than the Irish themselves. The effects of this unjust and impolitic ordinance were not long in showing themselves. A common interest united the descendants of the old settlers into a general combination. Alarmed at the spirit which they indicated, the lord-justice, Sir John Morris, deemed it expedient to assemble a parliament at Dublin, whereby a less dangerous vent might be afforded to the expression of the grievances of the discontented. But the injured party adopted another and a more spirited course. Not content with absenting themselves from parliament, they held another assembly, totally independent of it, at Kilkenny, under the auspices of the Earl of Desmond, in which they drew up a remonstrance, to be presented to the king, which exhibited a striking view of the aggressions of the government, and the grievances which had excited general discontent. The king's answer was gracious and condescending. Assurance was given them of immediate relief from the more gross grievances, and of inquiry into all. His anxiety to procure aid for his continental expeditions appears to have been one cause of the readiness with which these concessions were granted; for we are informed that the Earls of Desmond and Kildare attended him with numerous followers into France, and the latter distinguished himself greatly at the siege of Calais. But the spirit of self-interested monopoly which gave birth to this distinction, though repressed, was not extinguished; and fresh occasion was soon given it to blaze forth from a quarter whence it might least have been apprehended. Lionel, afterwards Duke of Clarence, Edward's second son, had married the heiress of the late Earl of Ulster, and thus became entitled to the lordships of Ulster and Connaught. To add weight to the enforcement of his claim, which he was about to assert in person, the king invested him with the lord-lieutenancy of Ireland. But, born and educated in England, he carried over with him all his English prejudices and prepossessions. Surrounded by men of English birth, and taught by them to look on the ancient settlers, not only as unworthy of his confidence, but as disaffected to his government, he forbade, by proclamation, any of the old English, or of the king's subjects of Irish birth, to approach his camp. This imprudent measure deprived him of the only aid which could render his operations against the common enemy of the English government effectual. Left, amongst strangers to the country, to traverse unknown districts, and to contend against an enemy of whose movements and mode of action he was wholly ignorant, he found himself enclosed in a position in which advance was impossible and retreat perilous, and from which he was extricated solely by an appeal to those whose services he had at his first landing so haughtily and unwisely rejected. After a short stay he was recalled, but returned in a few years, improved in the knowledge of the science of governing a country of habits dissimilar to those of his own. On his second visit he directed his attention to the general reformation of the parts of the island that yielded a willing obedience to the royal authority. A parliament was summoned at Kilkenny, the result of whose deliberations was an ordinance, since known by the name of the Statute of Kilkenny, which forms one of the great political epochs in the history of the country.

By this statute it was enacted, that marriage, fostering, or gossipred with the Irish, should be deemed treasonable; and conformity to the rules of Irish law was subjected to a similar penalty. The use of Irish names, language, or apparel, by any person of English birth or descent, was punishable by forfeiture of lands or imprisonment. Penalties were also imposed on those who permitted their Irish neighbours to graze on their lands, who presented them to ecclesiastical benefices, who admitted them into religious houses as members, or who gave encouragement to the Irish bards, musicians, or story-tellers. The execution of this statute was enforced by the anathemas of the church against its violators. Whatever might have been the effects of an enactment so rigorous towards uniting the English settlers more closely among themselves, it is evident that it severed completely any links of the bond of mutual charity and community of interests that existed between them and the Irish. The presence of an English nobleman of royal birth, connected by marriage with the descendant and representative of a family now nearly Irish through length of residence, might have led to the introduction of a system of generous equity towards the natives of the country, the former rightful possessors of the soil. But the wording of this statute pronounced the Irish to be irreclaimable. The opportunity for the amalgamation of conflicting interests was lost; and ages passed over without another such presenting itself for a renewal of the experiment. The Duke of Clarence was again recalled, and the administration of the government left, as before, to deputies. The low condition to which the country was now reduced may be inferred from the fact related as to Sir Richard Pembridge, warden of the Cinque Ports, who, on being appointed to the lieutenancy, refused to undertake the office, in consequence of the distracted state of the country; and it was adjudged that his refusal was strictly legal, inasmuch as residence in Ireland, even in the elevated station assigned to him, was looked upon as but an honourable exile, to which no freeman was to be subjected, except in case of abjuration for felony, or by act of parliament. So far was the English power reduced towards the close of this reign, that, as the authority of the English law had extended during the time of John over the twelve counties already named, and over the greater part of Connaught, it was confined, in the thirtieth year of the present reign, to the four counties of Meath, Louth, Dublin, and Carlow; and of these the greater part was border-land, governed by march law, which was little more than another word for the arbitrary will of the lord of the marches. The last effort made by Edward to restore the English government, was a mandate directing a stated number of bishops, knights, and burgesses to attend the king in his parliament in England, to assist in enacting laws for Ireland. The proceedings of this parliament are lost, but the existence of writs to the several counties, cities, and boroughs, directing them to defray the expenses of the persons sent over, proves that it had assembled. About the same time the trade with Portugal was thrown open to the Irish, but the disorders of the country were too deeply rooted to admit of the people availing themselves of the privilege.

In the beginning of the reign of Richard II., Robert de Vere, earl of Oxford, was appointed lord-lieutenant of Ireland by the joint consent of the king and the English nobility; the latter party wishing thus to break the connection of favouritism that bound him to the former. But after an equipment, fitted out on a princely scale, the project failed. He had proceeded as far as Wales, when Richard, who accompanied him to the water's edge, found his attachment too violent to bear the separation, and brought him back to London. Commissioners were afterwards deputed to inquire into the state of the country, but with no beneficial result. At length Richard resolved to visit this part of his dominions in person. He landed at Waterford with an army of four thousand men-at-arms and thirty thousand archers; but after nine months spent in an empty display of regal pageantry, during which he received the submission of seventy-five native Irish or degenerate English chieftains, and granted pardons to others, whom an apprehension of ill treatment kept at a distance, he returned to England. The only stipulation for restoring tranquillity made during his visit was, that the province of Leinster should be evacuated by the Irish; but when the condition was to be enforced, after the removal of the terrors of a royal army, the requisitions of the government were followed only by excuses and delays, and ultimately by insurrection, in the course of which Roger Mortimer, earl of Marche, whom Richard had left behind him as his lieutenant, was killed at Kenlis, in a skirmish against the O'Byrnes, whom he had driven from their mountain fastnesses in Wicklow.

Mortified and irritated by a result so contrary to the anticipations entertained from his expensive armament and pompous reception in Ireland, Richard undertook a second military expedition thither. He landed again in Waterford, and after spending some time there and at Kilkenny, in an idle display of royalty, he proceeded to Dublin, in the full confidence that now, as previously, his journey thither would be but a progress of pacific parade. In this expectation he was buoyed up by the appearance of several of the Irish lords, who, presenting themselves with halters round their necks, fell at his feet and implored forgiveness with the most abject humility. But on entering into the woods and defiles of the marches of Leinster, his reception was very different. M'Murchad, the principal chieftain of the province, who, notwithstanding the pensions he had received, and the submissions he had entered into, was still the inveterate enemy of the English, rushed out unexpectedly from the cover of his woods, at the head of three thousand chosen men, so well appointed, and with such a display of valour, as to stop the advance of the royal army for some time; and though it ultimately forced its way to the capital, such were the losses sustained by famine, hardship, and battle, that Richard had to wait for a reinforcement from England before he could resume hostilities. In the mean time the news of the successes of the Duke of Lancaster compelled him to hasten his departure, in order to oppose this new enemy. The unfortunate and disgraceful termination of his reign belongs to English history.

The intestine commotions in Ireland were aggravated in the reign of Henry IV. by invasions of the Scotch, who assisted the Irish of Ulster in driving the English from this province, and acquired some settlements there, whence they were never afterwards wholly removed. Henry's second son, Thomas, duke of Lancaster, was sent over as lord-lieutenant. His government was vigorous, and in some degree effective. The native Irish of Wicklow were checked; the degenerate English in Meath and Uriel were compelled to submit; and M'Murchad, who still maintained himself in the western parts of Leinster, in defiance of the government, was defeated in a severe and well-contested battle. The citizens of Dublin fitted out several naval expeditions against the Scotch and Welsh; and though, in their first engagement with the former enemy, they suffered a total defeat on the coast of Ulster, they afterwards revenged the insult by carrying the war into the islands and coasts of Scotland, and by their depredations in Wales, whence they brought back in triumph a shrine of St Cubin, and lodged it with much ceremony in Christ Church, as a proud monument of their victory. But this favourable change was merely temporary. The lord-lieutenant was wounded, and his forces beaten back, under the very walls of Dublin; and he soon afterwards quitted the country altogether. The residents in the border counties were now reduced to the degrading necessity of purchasing peace and protection from the neighbouring Irish chieftains, by the payment of a stipulated tribute called black rent.

The arrival of Sir John Talbot, Lord Furnival, in the succeeding reign, a man distinguished for his military talents, gave hope of a change for the better. By his activity and valour he compelled several of the neighbouring Irish chieftains, not only to desist from their incursions, but also to do homage and give hostages. Yet though bound to keep the peace, they still retained their independence,

History.

and the English pale was not enlarged. The lord-lieutenant, likewise, having brought with him no supplies either of men or money, had no means of maintaining his position, except the oppressive and ruinous system of coygne and livery. The English settlers were thus reduced to a state of extreme degradation and distress. Looked upon by the Irish as aliens and intruders, they were treated by the new comers from England as slaves, and considered by the English in general as in nowise better than the natives. In the beginning of this reign, the parliament at London, in consequence of the swarms of needy adventurers from Ireland, whom the devastations of their own country had driven to seek an asylum abroad, passed an act to oblige all Irish to quit the kingdom. Even the students who resorted to London for education, though expressly excepted from the severe provisions of the statute, were contemptuously excluded from the Inns of Court, from a prejudice as impolitic as it was unjust, since it not only precluded them from an intercourse tending to conciliate their affections to England, but debarred them from the means of acquiring a knowledge of the laws, which were the only effective means of preserving the connection between the countries. Indeed the continuance of such connection was preserved at the present period, more by the ignorant prejudices of the native princes themselves, than by the exertions of the government. Contented to rule over their petty septs, their aversion to the English was scarcely more violent than that entertained by them against the neighbouring tribes of their own race. They united in the most cordial attachment with the old English in their revolts; and their insurrections, far from being excited by a general desire of exterminating the whole body of their invaders, were usually occasioned by some local dispute or act of private oppression.

In the beginning of the reign of Henry VI. the two Anglo-Irish families of Desmond and Butler began to assume the high political position which they retained long after. James, the first Earl of Desmond, obtained the leadership of the family and the title, to the prejudice of his nephew, who had degraded himself in the eyes of his followers by marrying a peasant's daughter. The uncle was secured in the estate by authority of parliament, and also constituted governor of the counties of Waterford, Cork, Limerick, and Kerry, over which he exerted an almost royal jurisdiction. The Earl of Ormond, the head of the Butler family, after having been removed from the chief government of Ireland by the machinations of his enemies, was protected against their further efforts by the personal kindness of Henry VI., which laid the foundation of a lasting attachment to this monarch on the part of the earl and his descendants. A change now took place in the government, more important in its effects than any hitherto recorded. Richard duke of York, descended from an elder brother of the prince through whom the reigning family derived its claim to the throne, was universally beloved. The contrast between him and his inglorious sovereign was too glaring to remain unnoticed. It was therefore resolved to remove him out of England; and he was appointed lord-lieutenant of Ireland, with extraordinary powers. His administration presents one of the few bright gleams of Irish history. It was long quoted as the time when peace and prosperity flourished, when faction was repressed by even-handed justice, and when the natives, the English by blood, and the English by birth, coalesced in an honest exertion to improve the country. Aware, on his arrival, of the bitter jealousy which existed between the rival families of the Butlers and Geraldines, and although he knew that the former was attached by gratitude to his rival, he scorned to be swayed by any suspicions on that account; but, on the birth of his son, afterwards the unfortunate Duke of Clarence, by engaging the heads of both families to be sponsors at the infant's baptism, he bound each to himself and to the other by the tie of gossipred, a relationship respected to a degree of veneration amongst the Irish. Being called away to England to clear himself from some imputations on his loyalty, he intrusted the administration to the Earl of Ormond, who was succeeded by Sir Edward Fitz-Eustace, a knight of great military fame, by whom the O'Connors of Offaly were defeated, and the sept of the O'Neills, who had presumed to insult the city of Dublin by plundering some of the ships in the bay, and carrying off the archbishop, were so roughly treated at Ardglass, as to check for a long period any efforts of the northern toparch against the pale. In the mean time the Duke of York, though successful in his first effort to seize the English crown, was totally defeated at Bloreheath, and forced to fly into Ireland, where he was received more like a sovereign prince than a discomfited traitor. The parliament passed an act for his protection, and decreed that whosoever should attempt to disturb him, under pretence of writs from England, should be deemed guilty of high treason. An agent of Ormond, who ventured to violate the law, was executed. On the duke's subsequent change of fortune, numbers of his Irish adherents followed him to England. The palatinate of Meath, in particular, was almost deserted by the English settlers, who hastened to enrol themselves under the banner of the white rose. He appeared in London with this gallant train; but the war being unexpectedly renewed, he was encountered at Wakefield by an army four times more numerous than his own, which consisted but of five thousand men, mostly Irish, and fell in the unequal contest, together with the greater part of his devoted followers. The exhaustion thus produced was nearly fatal to the English interests in Ireland. Towards the close of Henry's reign, the Irish or rebellious English had conquered or subjected to tribute the greater part of the counties of Limerick and Tipperary, together with those of Kilkenny and Wexford, and almost the whole of Carlow, Kildare, Meath, and Uriel, so that little was left, of which the English could claim the undisputed possession, excepting the county of Dublin. The only method to secure peace was by the purchase of the protection of the heads of the Irish septs, who, gratified with such acknowledgment of their superiority, looked with contemptuous disregard on the movements of the Saxons, as the English were called by them.

The attachment of the Geraldines to the house of York was rewarded by Edward IV. on his attainment of the royal dignity, by appointing the Earl of Kildare to the lord-lieutenancy. He was shortly afterwards superseded by the Duke of Clarence, the king's brother, who appointed the Earl of Desmond his deputy, in return for having crushed an effort made by the Butlers in favour of the house of Lancaster. But his continuance in power was short-lived. On the king's marriage with Elizabeth Grey, he had incautiously thrown out some reflections upon the meanness of her birth. Tiptoft, earl of Worcester, was soon afterwards sent over as lord-deputy, and, in a parliament summoned at Drogheda, he caused an act to be passed against the Earls of Kildare and Desmond, for allying themselves by marriage, and fostering with the Irish enemy. Kildare, though arrested, was fortunate enough to effect his escape. Desmond, relying either on his innocence or his influence, came forward to justify his conduct, and was immediately seized and executed without even the formality of a trial. This monstrous outrage did not long go unpunished. Kildare justified himself so effectually before the king, that he was not only restored to his titles and estate, but appointed chief governor; and Tiptoft, being recalled into England, suffered, in a new revolution, the same fate which he had inflicted upon Desmond. The defence

History.

of the confined limits of the pale was now intrusted to a military order established by authority of parliament, under the name of the Fraternity of St George. It consisted of thirteen leaders of the first consequence in the four counties of Dublin, Meath, Kildare, and Uriel, who had under them forty knights, as many squires, and an hundred and twenty mounted archers. The appointment of a force so inadequate to preserve the peace even of the contracted limits it was intended to protect, evinces in the strongest manner the reduced state of the English power after the termination of the desolating conflict between the rival roses.

The short and distracted reign of Richard III. allowed no time to attend to the state of Ireland. His successor, for what reason it is not known, suffered the government to continue in the hands of the Fitzgeralds, the avowed friends of the house of York. The evil consequences of this policy, or negligence, were not long in showing themselves. Lambert Simnel, who had been set up by the king's enemies on the Continent to personate the Earl of Warwick, son of the late Duke of Clarence, was sent by them to Ireland, as the place most favourable for the design. He was received by the Earl of Kildare, then lord-lieutenant, as the lawful sovereign; proclaimed king; publicly crowned in Christ Church, with a crown taken for the purpose from a statue of the Virgin Mary; and borne thence to Dublin Castle on the shoulders of Darcy of Platten, according to a form used in the inauguration of the native Irish kings. A parliament convened by his writ, under the title of Edward VI. granted subsidies, and enacted severe laws against those who refused to recognise his right, amongst whom the chief were the families of Butler and Bermingham, and the citizens of Waterford. Fortunately for the peace of the country, the arrival of a body of German auxiliaries from Flanders, under the command of Martin Swart, inspired the partisans of Simnel with such an overweening confidence in their own strength, that they determined to transfer the seat of war to England. Thither Simnel went, attended by the flower of the Irish nobility, and a numerous following of the natives. He was met at Stoke, in Nottingham, and defeated by Henry with immense loss, as the Irish, whose light arms could make no impression on the compact and iron-bound ranks of their adversaries, refused quarter, defending themselves singly, even when routed, until they fell overwhelmed by numbers. Simnel, when taken prisoner, was punished, not by severity, but degradation. He ended his life as a scullion in the royal household. The actors in this hasty and ill-digested movement were not treated harshly. Even the city of Dublin was pardoned, on its humble submission. But, in the hope of securing the future allegiance of the great residents, Sir Richard Edgecombe was sent over as a special commissioner, with a train of five hundred men, to receive their submission, and administer the oath of allegiance. On his arrival at Kinsale, his apprehensions at first prevented him from landing; and he received the homage and oaths of Lord Thomas Barry, a principal nobleman of the district, on board his ship; but afterwards landed, and was received in Cork, Waterford, and Dublin, in a manner befitting his mission. The Earl of Kildare hesitated for a time, but at length joined with the others in tendering this proof of submission to the ruling power.

Another claimant of the throne now appeared in the person of Perkin Warbeck, who was, or pretended to be, the Duke of York, second son of Edward IV. He landed at Cork, where his identity was acknowledged. On his arrival there he wrote to the Earls of Desmond and Kildare. The former recognised him at once; but before the latter could decide on the part he ought to take, the adventurer had removed to the French court, whither he had been invited for the purpose of more effectually annoying the English king. Henry now sent over into Ireland Sir Edward Poynings, a knight of distinguished ability, accompanied by several English lawyers to fill the offices of judges; those then on the bench, who owed their elevation to party influence, being notorious for their incapacity.

The administration of this governor forms a new era in the history of the country. A parliament assembled by him enacted several useful laws, two of which were peculiarly influential in breaking down the exorbitant power of the nobility. By one of these, all the statutes hitherto passed in England were made law in Ireland; by the other, it was enacted that no parliament should be held until the reasons for holding it, and the statutes to be proposed in it, should be approved by the privy council of England. Warbeck made a second attempt upon Ireland, in which he was openly assisted by the Earl of Desmond; but after an unsuccessful attempt on Waterford, he was forced to quit the country, and take refuge with the king of Scotland. The enemies of Kildare were not remiss in seizing this opportunity to crush him; and the Butlers importuned the lord-deputy to imitate the example of Tiptoft, and consign him at once to the executioner. But Poynings rejected the cruel and impolitic suggestion, contenting himself with sending the earl to England to answer in person the allegations brought against him. This proceeding, as just as it was merciful, led to a conclusion wholly opposite to the anticipations of his enemies. When warned by the king to choose able counsel to defend himself against the heavy charges advanced against him: "Yes," said Kildare, "I choose the ablest in the realm; I take your highness as my counsel against these false knaves." Charge after charge was alleged against him, and answered; amongst others, that of having burned the church of Cashel. On hearing this brought forward, Kildare interrupted the speaker: "Spare your evidence," said he; "I did burn the church, but I thought the bishop had been in it." This extraordinary plea raised a laugh amongst all present. His accusers in a rage exclaimed, "All Ireland cannot rule this earl." "Is it so?" replied Henry; "then this earl shall rule all Ireland;" and he sent him back as lord-deputy. The event justified Henry's sagacity. Kildare repaid his sovereign's confidence by a government of unremitting zeal, energy, and fidelity. The boundaries of the pale were gradually extended; several septs, to whom tribute had hitherto been paid, were forced to submit. He marched a gallant army into Connaught, against Ulick de Burgho, the head of the degenerate English in that province; more, it must be acknowledged, to gratify private resentment than to promote the interests of his royal master. The armies met at Knocktow, near Galway. The victory of the deputy was sullied by the ferocity of his troops, who refused to give quarter, and continued the massacre until night forced them to desist. This victory reduced the whole of Connaught to obedience. The O'Neills and the O'Briens were the only septs of any consequence who still refused to tender their allegiance.

The Earl of Kildare was continued in the government by Henry VIII., who testified his approbation of his services by appointing his son Gerald his successor. The young earl, with the characteristic valour of the family, inherited a more than ordinary share of their pride and imprudence. Too haughty to court the favour of Wolsey, then in the zenith of his greatness, by meanness and subserviency, he incurred that proud prelate's hatred, which was heightened by the artful suggestions of his rival the Earl of Ormond. Through the machinations of this nobleman he was removed, and summoned to England to account for his conduct. Here, strengthened by a marriage with the daughter of the Marquis of Dorset, he was enabled to baffle the efforts of the cabal formed against him.

He attended Henry at his celebrated interview with Francis I., and, by the splendour of his suite, and the brilliancy of his equipage, contributed largely to the splendour of "the Field of the Cloth of Gold." On his return home, the struggle between the rival families attained to such a height, that commissioners were sent from England to investigate the case. Their report, when laid before Henry, induced him to remove from the head of affairs Pierce earl of Ormond, better known in the chronicles of the times by the name of Red Peter, the deputy to the Earl of Surrey, then lord-lieutenant, and to substitute his rival in his place. The decision proved eventually fatal to this nobleman. Inflated with an opinion of his own greatness, he acted so as to excite a suspicion of aiming at the assumption of independent power in Ireland. His enemies pressed the charge against him, and a peremptory order was issued for his immediate attendance at court. Unwilling to quit the seat of power, conscious most probably that his conduct would not bear a strict investigation, he endeavoured, through his wife's relations, to evade obedience; but finding all his efforts ineffectual, he ultimately repaired to London, after having supplied all his castles with arms and ammunition from the royal stores, a measure tending most powerfully to confirm the prejudice raised against him. On his arrival there he was forthwith thrown into the Tower.

That the royal anger against the earl had not been very violent, is evident, notwithstanding the harsh treatment thus inflicted on him, from the fact that he was permitted to commit the government during his absence to some person for whose conduct he should be responsible. By a step still more unaccountable than any of those that had involved him in suspicion, he intrusted the administration to his eldest son Thomas, a stripling scarcely twenty-two years of age, who, to the rashness of youth, and a natural violence of temper, added an insolent contempt of his rivals, and a boyish confidence in the irresistible power of the Geraldines. The news of his father's imprisonment could not fail soon to arrive in Ireland. Common fame, aided by the artifices of the enemies of the family, swelled it into an assertion of his execution. The young lord lent a credulous ear to these falsehoods, and, as impetuous as he was credulous, instantly had recourse to means of vengeance as desperate as they were chivalrous. Attended by a retinue of an hundred and forty followers equipped in a style of gaudy display, which, even in those times of courtly splendour, earned for him the title of "the Silken Knight," he proceeded to St Mary's Abbey, on the northern bank of the Liffey, where the privy council were assembled; and there, throwing down the sword of state, he solemnly renounced his allegiance, and declared himself the mortal enemy of the English government. All the other members of the council gazed on him in silent astonishment. Archbishop Cromer, then primate and chancellor, alone interfered, and remonstrated with the fiery young man on the madness of the act he was committing. The appeal to his better judgment was interrupted by the family bard, who, unconscious, through his ignorance of the language, of what was going forward, commenced a rhapsody on the glories of the Geraldines, the treatment of their chief, and the vengeance which it claimed. Passion prevailed over prudence. The voice of age and wisdom was drowned in the clamours of his attendants, and the young lord tore himself from the chancellor, rushed out of the council board, and, without premeditation or preparation, plunged into a war against the whole power of England.

Baffled in an attempt to surprise the castle of Dublin, Lord Thomas ravaged all the district of Fingal, in its northern neighbourhood, during which Alen, archbishop of Dublin, one of the determined enemies of his family, was taken prisoner. When brought before him, his hasty expression, "Away with the English churl," was translated by his rude Irish followers into a mandate for execution, and the wretched man was immediately butchered. He then renewed his attempt to seize the castle, but was prevented, and eventually driven from the city by the citizens, who even burned part of the suburbs, to prevent them from affording shelter to his troops. From being the aggressor, he was now forced to act on the defensive. Maynooth Castle, his strongest fortress, was invested, and, after a resistance of fourteen days, was captured by the treachery of a foster brother of Lord Thomas, who, after having been paid the pecuniary remuneration of his treason, received a more adequate recompense by being hanged by the orders of the English deputy. The irregular army of the insurgents began to dissolve on the intelligence of this disaster, and their leader was driven to a desultory warfare in the fens and mountains, from which he was inveigled by a solemn assurance of pardon given by the English general Lord Grey, and confirmed by the communion of the holy sacrament. Grey was rewarded for his services by the office of lord-justice. His first act of government was one of atrocious perfidy. In spite of his previous solemn promise, he sent his prisoner to London, where the first news the wretched youth received was, that his father had died, not by legal execution, but through grief at his insane rebellion. This act of Grey was followed by a similar one, if possible of deeper guilt. Henry breathed the most furious revenge against the whole family of Kildare, and sent orders to have the five uncles of the young lord seized. To effect this, the lord-deputy invited them to a banquet, where, in the midst of the pretended hospitality, they were arrested, forced on board ship, hurried to England, and executed along with the real instigator of the rebellion. A brother of Lord Thomas, a boy about twelve years of age, who was also included in this decree of blood, after having been sheltered for some time, at no small risk, by his aunt, the widow of M'Arthy, a Munster chieftain, was conveyed to France, and, when Henry had the meanness to claim him as a subject, he escaped to Flanders. Thence, when pursued by the same spirit of despicable malignity, he fled to Germany, and finally found shelter in Rome, under the protection of Cardinal Pole, who, in defiance of Henry's protestations, received and educated him as his kinsman, and, by his favour and support, enabled him to recover his birthright, and restore the otherwise extinct honours of the house of Kildare.

A period now arrived in which religion, hitherto little noticed in the political events of the country, was forced to assume a character as dissonant to its real nature as prejudicial to its true interests. Henry determined to extend to Ireland the reformation he had with so little opposition established in England. Commissioners were sent over to procure an acknowledgment of the king's supremacy, who, though opposed by Cromer, the archbishop of Armagh, a strenuous champion for the religion at that time established by law, succeeded in obtaining it. A parliament, assembled at the special suggestion of Browne, the first Protestant archbishop of Dublin, exhibited a subserviency to the royal wishes as great as even the despotic character of Henry could require. It pronounced the king's marriage with Catherine of Aragon null; declared the inheritance of the crown to be in the king's heirs by Anne Boleyn; and as the passing of this declaration was followed by an account of that unhappy lady's condemnation and death, and the king's subsequent marriage with Anne Seymour, it altered the succession anew to correspond with the new change in the king's disposition. It also acknowledged the king's supremacy in the fullest manner, forbade appeals to Rome, renounced the authority of the Romish see, and decreed the suppression of most of the monastic institutions.

An act, more creditable to the body whence it emanated, was also passed, by which schools were to be founded in every parish for instructing the natives in the English language, and in the rudiments of useful knowledge.

But words and writings were not of themselves sufficient to accomplish the mighty undertaking which Henry's impetuous zeal had commenced. The Irish clergy in general were averse to a change. Many of them relinquished valuable preferments rather than submit to it. The Irish chieftains found in it a new motive to animate themselves and to influence their followers against the Saxons. The feeling was fomented by a communication from Rome, exciting the northern chieftains, and more particularly O'Neill, to rally round the sacred standard of their forefathers. O'Neill joyfully accepted the post thus assigned him. He proclaimed himself head of the northern Irish, assembled a numerous force, advanced to Tarah, and there had himself proclaimed on the ancient hill of royalty of the native monarchs of Ireland; but, content with this idle display of pomp, he prepared, after ravaging the country, to return into his own demesnes. The deputy had expected this storm, and was prepared against it. With the forces raised in Dublin and Drogheda he pursued the retiring Irish, and overtook them at Bellahoe, on the borders of Meath, where, after a partial engagement, in which the van of the latter army only was concerned, the Irish fell back on their main body, which, struck with an unaccountable panic, immediately gave way and fled. The administration of Lord Grey ended with this victory. He was recalled, and thrown into the Tower, on charges equally futile and malicious. Apprehensive of the irritable temper of his brutal master, he waived all defence, pleaded guilty, and perished by the same fate into which he had so treacherously drawn Lord Thomas Fitzgerald and the rest of the ill-fated Geraldines.

The next step taken by Henry to complete the tranquillization of Ireland, was the assumption of the royal title. Hitherto, though exercising all the essentials of sovereignty, the kings of England had contented themselves with the title of lords of Ireland. This term was now changed by act of parliament into that of king. The alteration was commemorated by conferring peerages on several of the heads of the great families. O'Neill was made Earl of Tyrone, with the singular privilege of transmitting the title and estate to an illegitimate son, to the prejudice of his lawful issue. Ulick de Burgho was created Earl of Clanricarde, and O'Brien Earl of Thomond. Several of inferior note were created barons. Besides the act declaring the king's regal title, others, to the following purport, give striking indications of the manners of the times: Laymen and boys were excluded from ecclesiastical benefices; homicide and robbery were punished by fine, wilful murder and rape by death; coygne and livery were prohibited, unless by command of the lord-deputy; idle men and retainers were forbidden; noblemen were allowed no more than twenty cubits or bandles of linen in their shirts, which were not to be dyed with saffron; and the people of a country into which a theft was traced, were to trace it thence, or make restitution. A glaring omission in these statutes rendered them almost nugatory. Whilst the great lords were rendered more dependent on the crown by the abolition of their ancient tenures, no provision was made in favour of the subordinate chieftains, or the great mass of the population, over whom their ancient masters were still permitted to exert their former arbitrary dominion. Neither was this omission caused by inadvertence. The petitions of the natives to be governed by English law were disregarded or denied. O'Byrne, the head of a sept which had long kept the capital in a state of alarm, vainly petitioned that his territory should be converted into an English county by the name of Wicklow. A similar proposal for the Annaly, from its proprietors the O'Ferrals, was treated in like manner, although the king, when applied to, had acquiesced in the arrangement. The only territorial change ventured upon by the lord-deputy was the division of the territory of Meath into the counties of East and West Meath. Still, however, the civil reformation of the country was in progress. A state of general tranquillity was perceptible. Such, indeed, was the spirit of allegiance at this period, that Francis I. then at war with England, found it impossible to move the Irish to insurrection. On the contrary, Henry was attended to Calais on his French expedition by a considerable body of Irish troops, who distinguished themselves equally by their agility during the march, and their ferocity in the combat.

But the happy prospect which now began to dawn over the country was marred by the mismanagement of the English government. O'More and O'Connor of Offaly had renewed their incursions into Leinster. They were soon driven back into their fastnesses, whence they were lured, by a delusive expectation of pardon and favour, on condition of presenting themselves to the king. Scarcely, however, had they arrived at court when they were seized and thrown into prison, where the former soon sunk under the severity of his treatment. The disgust excited by this act of treachery was heightened by the manner in which the reformation was pressed upon the people. When Dowdal, the primate, who had succeeded Cromer, refused to countenance the new doctrines, an old controversy relative to the superiority of the sees of Armagh and Dublin was revived, and, by a royal patent, the title of primacy was transferred from the former to the latter see. Dowdal, unable to brook the indignity, peevishly as well as injudiciously deserted his see, and retired to the Continent. The opposite party, taking advantage of this false step, immediately placed Goodacre, a Protestant bishop, in the see he had abdicated. Throughout the country parts also, the removal of the clergy of the ancient faith, and the introduction of those of the new doctrines, were carried on in a spirit of violence and acrimony unbecoming the cause and irritating to the people. The garrison of Athlone attacked the ancient and venerated recess of Clonmacnois, plundered its furniture, defaced its ornaments, and defiled its altars. Similar excesses took place in other parts. Thus the impression made by those champions of reform was, that the new system sanctioned sacrilege and robbery. In the north, the general peace was disturbed by the family dissensions of the O'Neills. Shane or John O'Neill, the legitimate son of the first Earl of Tyrone, laboured sedulously to induce his father to alter the arrangement which gave the inheritance to his natural son Matthew. The latter threw himself for protection on the lord-deputy, who could devise no better means for closing the family schism, than by seizing on the persons of the earl and his countess, whom he kept in close confinement. The consequence of this arbitrary act was the throwing the whole of that country into the hands of Shane, who claimed it by the principles of the English law, and who, assisted by a body of Scots, committed terrible depredations on the property of those who disputed his right or set his power at defiance.

A new revolution, occasioned by the death of Edward VI. added to this state of confusion. The religion was again changed. Dowdal was recalled to the primacy; the most violent of his opponents fled the country, and the great body of the clergy returned to their former faith. This restoration was attended with no acts of violence; the Protestants were not persecuted. On the contrary, several of the English, who had fled from the severity of the law in their own country, were received and sheltered by the Catholics in Ireland. Not so with the Irish. The septs of Leix and Offaly resisted the forfeiture of their lands. They insisted that the offences of their leaders ought not to involve in their confiscation the inferior heads. They took up arms in defence of their rights; but they were soon taught the futility of their opposition. An armed force was sent into the country, which proceeded in the work of extermination with such ruthless ferocity, that scarcely a remnant of the ancient residents could be found to avail themselves of the tardy pardons procured for them by the generous interference of the Earls of Kildare and Ossory. The territory was reduced into shire-ground, under the names of the King's and Queen's Counties, in honour of Philip and Mary, whose names were given to the respective assize towns of each.

Elizabeth, on her accession, found the whole island involved in a state of petty warfare. The Earl of Thomond contended with another branch of the O'Briens for the rulership of North Munster. The Desmonds and Butlers renewed their contentions in the south. M'William Oughter rose in arms against the De Burghos of Clanricarde. The dispossessed inhabitants of Leix and Offaly revenged themselves by the pillage of the neighbouring districts of Leinster, and Shane O'Neill was making rapid strides towards the sovereignty of the whole of Ulster. The last named of these parties was the first pacified. Sir Henry Sidney, the new lord-deputy, instead of turning the military force of the queen against him in the first instance, had recourse to gentler measures. Accepting an invitation to settle the matters in controversy at O'Neill's own residence, he was received with such splendid hospitality, and heard such a statement of facts, as induced him not only to relinquish all ideas of severity, but to engage to be his mediator with the queen. O'Neill even attended the lord-deputy to Dublin; but when there, being made more fully aware of the deadly machinations of his secret enemies, who thirsted to make his princely property an object of confiscation, he adopted the daring resolution of proceeding to London, and laying his case before the queen in person. Attended by a chosen band of followers equipped in the most appropriate costume of the country, he entered that city, to the astonishment and delight of the population, then as well as now fascinated by show and singularity. A native Irish chieftain, followed by a band of men armed in a strange fashion, with heads bare, their hair flowing in clustering curls on their shoulders, clad in saffron linen vests of exuberant folds, surcharged with light and polished cuirasses, and bearing broad double-edged battle-axes over the shoulders, caught the fancy and dazzled the imagination, not only of the populace, but of the queen herself. She received the singular visitant with marked favour, and sent him back to Ireland secured in the possession of the title and property which he claimed as his right upon his father's death. But this unexpected tide of royal favour only whetted the ingenuity of his enemies at home. Complaint after complaint, either of actual offence or of imputed ill intention, was sent over to Elizabeth, whose answer, "that if he revolted it would be better for her servants, as there would be more forfeitures to divide amongst them," excited their hopes, as the prospect of the prey had roused their cupidity. Sir Henry Sidney had placed a garrison in the town of Derry. This step O'Neill considered as an infringement of his rights, and an intrusion on his sovereignty. A body of forces led by him against it defeated and slew the governor. Shortly afterwards, the church, which had been used as a powder magazine, was blown up by accident, and the garrison forced to evacuate the place. This event was construed by the people into a judgment from heaven for the profanation. O'Neill then proceeded to Armagh, which he took by storm, and burned the cathedral; but was baffled in a subsequent attempt upon Dundalk. The tide of fortune now set strongly against him. Several of the native chieftains in the north, and Desmond in the south, took part with the government. His forces were unequal to contend against such a combination. Finding resistance hopeless, his first emotion was to throw himself on the mercy of the lord-deputy; but the treatment of O'More under similar circumstances deterred him. He therefore determined to seek the protection of a body of Scotchmen, who were encamped in that part of Antrim then known by the name of Claneboy. His proposal of joining this party, which was readily accepted by them, became known to the English governor, who sent an officer of the name of Piers to the Scotch commander, to persuade him to assassinate his unsuspecting guest. The plot succeeded. O'Neill, on his arrival, was assailed by a party of his host's followers, upon the futile pretence of a sudden quarrel during the entertainment to which he was invited. His head was sent to Dublin, and Piers received a thousand pounds for his share in the transaction. The deputy named a feeble old man, named Tirlogh Leynagh, as head of the sept, to prevent this office being filled by a more youthful and daring individual.

The ruin of O'Neill in the north was followed by that of Desmond in the south. A small body of Spaniards was brought into that part of Ireland by a banished branch of the Fitzgerald family. Though the Earl of Desmond steadily persevered in avoiding to connect himself with their proceedings, the conduct of some of his relations involved him in suspicions, which were then nearly tantamount to guilt. His brothers Sir John and Sir James having joined the invading party, the former disgraced himself, and injured his cause, by the unprovoked murder of an English gentleman of the name of Davels, who had been sent by the deputy to persuade them to continue in their allegiance. The whole force of the government was directed against the family. The army of the insurgents was utterly routed at Kilmallock. The earl himself, though as yet guilty of no overt act, received a peremptory order to surrender within twenty days; and upon his declining to appear, he was declared a traitor. The war was carried on against him with unexampled cruelty. Slaughter, fire, and famine, desolated the finest parts of the rich province of Munster. Desmond, driven to desperation, made a vigorous stand. At one time he possessed himself of the town of Youghal, but was soon afterwards defeated by his old and bitter enemy the Earl of Ormond. At this time a new lord-deputy was sent over in the person of Lord Grey. His first effort was an attack upon the O'Byrnes of Wicklow, who were charged with having banded themselves in alliance with Desmond. He determined to attack them in their stronghold of Glendalogh, in the very centre of the mountains; but, when entangled in the inextricable labyrinths of these mountain fastnesses, he was assaulted with such well-judged fury, that his army was cut off almost to a man, he himself scarcely escaping to Dublin, overwhelmed with shame and confusion. Hence he was soon afterwards called away to Munster. A body of Spaniards seven hundred strong had arrived in Kerry to the aid of Desmond; but the number was too small to be effective. On their landing they secured themselves in an intrenchment, which they named Fort d'Ore. Here they were blocked up by the lord-deputy, so as to render escape impossible. They surrendered, whether on terms or at discretion is uncertain. But the subsequent atrocity is as certain as it is detestable. Lord Grey ordered the whole of the garrison to be butchered. His instructions were executed to the letter. Sir Walter Raleigh, and Spencer the poet, were involved in the infamy of this abominable act, the one as the officer presiding at the massacre, the other as assisting in the councils where it was devised. The war was now at an end, but the chief victim still found means to avoid the indefatigable pursuit of his enemies. Hunted from lair to lair, he suffered all the extremity of famine. A few of his daring adherents had seized a prey of cattle for his sustenance. They were traced into a wooded valley, where, attracted by a light, his pursuers were led to a hovel, in which they found only a feeble old man. On being assaulted and wounded, he called out for mercy, and told them he was the Earl of Desmond. This was the signal for his death. The soldier repeated his blow, and slew him. His head was forwarded to the queen, who ordered it to be fixed upon London Bridge.

The government of Sir John Perrott, who succeeded Lord Grey, presents one of the bright spots in the history of the country. His first act was to publish an amnesty, and to denounce the military slaughters and spoliations which were encouraged by too many of the commanders. He took care to secure all parties in their persons and properties, to administer justice to all alike, and to reform the gross abuses in the public departments. Nor were his endeavours unsuccessful. The natives vied with each other in tendering proofs of loyalty. The old lords of the pale suspended their feuds, and came up to attend his court in Dublin. A parliament was assembled, which, though with some reluctance, passed an act for the attainder of the deceased Lord Desmond, together with an hundred and forty of his followers, and confiscated his immense estate to the crown. Having thus reduced the south to order, he turned his attention to Ulster. Hugh, the eldest son of Matthew, Lord Dungannon, was entitled to the honours and estates belonging to the earldom of Tyrone. He had been educated in England, and had served with honour in the queen's army. He now applied for his seat in the House of Lords, and for the restoration of his property. Perrott granted him the first of these requests, and referred him to the queen as to the second. He therefore presented himself at court, not, like his predecessor, in the wild attire and equipage of an Irish dynast, but as a British courtier. He was received with marked partiality, and soon restored to his possessions. The close of Perrott's government was stained by an act unworthy of him. O'Donnell, the chieftain of Tyrconnel, was suspected of meditating a revolt. Perrott undertook to stifle the attempt without difficulty or expense. To effect this, he caused O'Donnell's eldest son to be inveigled on board a ship sent into Lough Swilly, on pretence of trafficking in wine, and had the young man brought up to Dublin, where he was kept for some time in close confinement. But such had been this governor's general conduct, that even an act so unjustifiable did not deprive him of general confidence. On his recall, being aware of an impending Spanish invasion, he assembled such of the lords and chieftains as were most likely to be swayed from their allegiance by the appearance of a foreign force, pointed out to them the consequences which must result from the apprehended invasion, and persuaded them to give hostages in proof of their determination to adhere to their sovereign. He then quitted the country, followed by the blessings and prayers of thousands. The conduct of his successor, Sir William Fitzwilliam, whose sole object appeared to be the accumulation of wealth, enhanced the feelings of regret for his departure. After the defeat of the Spanish Armada, several of the ships belonging to it were lost on the northern coast of Ireland. Reports were rife as to the quantities of money acquired from the wrecks by the chieftains residing in the neighbourhood. Fitzwilliam seized upon some of them, on the mere suspicion of their being in possession of these treasures, and kept them for years in close confinement. He afterwards imprisoned M'Mahon, the head of the sept that held Monaghan county, on a charge of treason, for having employed a military force to collect his revenues, an usual custom in the Irish districts, and brought him to trial before a jury of soldiers, by whom he was at once condemned and consigned to immediate execution. These and similar severities excited the spirit which they professed to repress. Young O'Donnell, who had been treacherously entrapped by Perrott, found means to escape from Dublin Castle, and took refuge in the mountains of Wicklow, whence, after a year's residence, he made his way, through extraordinary difficulties, to his own country, where he was most active in fomenting the spirit of discontent amongst his neighbours.

About this time the university of Dublin was founded, on the site of a suppressed monastery. The project was first conceived by Sir John Perrott, but it was not acted upon until the time of his successor. It was the only successful effort since the arrival of the English at imparting to the country a knowledge of the higher branches of learning.

O'Neill, ever since his restoration to his estate, had been preparing means for the part he afterwards acted. Amongst the stipulations in his favour on his restoration, was the privilege of being attended with a certain number of armed men. These he frequently changed, so as to have in a short time a large number of his followers trained to the use of arms. When he conceived himself sufficiently prepared to set the English power at defiance, he threw off the mask, and openly laid siege to the fort of Blackwater, built some time before for the avowed purpose of keeping him in check. Sir Nicholas Bagnal was sent to relieve it. The opposing armies met near Armagh. The numbers on each side were nearly equal, but fortune turned the scale of victory. In the heat of the engagement, the explosion of a magazine threw the queen's forces into confusion. The death of Bagnal, who, whilst raising his visor, was shot through the brain, rendered the confusion irremediable. The victory of the Irish was decisive, and fifteen hundred of the enemy fell in the field. The fort of Blackwater immediately surrendered, and Armagh was evacuated by the queen's troops.

Elizabeth at length determined to make one irresistible effort to crush an adversary now become truly formidable. She sent the Earl of Essex into Ireland as lord-lieutenant, at the head of twenty thousand men; a number deemed more than sufficient to accomplish her object in a single campaign. Essex had orders to proceed directly against Tyrone; but he took a course diametrically opposite. He directed his march southwards through Munster, where he found an impoverished and depopulated country, and an enemy that eluded every effort to bring them into decisive collision. In passing through Leix, his cavalry suffered heavily from the repeated desultory attacks of O'More, who cherished all his ancestor's hereditary hatred of the English; whilst another division of his army was defeated by the O'Byrnes of the mountains. In another quarter Sir Conyers Clifford, who was sent into Connaught to create a diversion in favour of the main body, was routed and killed in the Curlew Mountains, by O'Ruark, prince of Breffney, as the county of Leitrim was then called. These repeated losses so diminished the numbers and broke the spirit of the English, that when Essex moved northwards to effect his main object, he found his means inadequate to the attempt. An interview was proposed and accepted, which was followed by a truce for six weeks, in consequence of which the English army returned to its quarters in Leinster.

The anger of Elizabeth at this termination of her expensive expedition was extreme. Essex, to ward off its effect, took the desperate expedient of returning unbidden to court, to justify himself in person. The act was as unfortunate as inconsiderate. He was arrested, imprisoned, and, on a still more frantic effort to excite the citizens of London against the queen, was tried and beheaded.

Sir Charles Blount, Lord Mountjoy, was sent to Ireland in the place of Essex. His love of literature had excited an opinion of his effeminacy. O'Neill exulted openly at the appointment of a man "who would lose the season of action whilst his breakfast was making ready." He was soon to learn that the graces of polite literature are by no means incompatible with the qualifications of a warrior. At the commencement of Lord Mountjoy's proceedings, an occurrence took place which excited in his mind strong doubts of the honesty of the Earl of Ormond, who had still the chief command of the army. This nobleman having allowed himself to be trepanned into a conference with O'More, the chieftain of Leix, on pretence of treating as to terms of submission, was seized and long detained prisoner, as Mountjoy was not over hasty in paying a large ransom for a man who, he shrewdly suspected, had been the secret cause of his own calamity. The proceedings against O'Neill were conducted with much policy. The inferior chiefs were bribed to join in the confederacy against him. Rival claimants were set up against his friends. The lands of those who adhered to him were mercilessly devastated. Pardon was granted to the insurgents only on the condition of betraying or murdering a relative or friend. A strict adherence to these practices soon wasted O'Neill's strength. He persevered in his resistance, however, in the hope of succours from Spain. These at length arrived, but fell far short of what his expectations had anticipated, or the greatness of the emergency called for. Two thousand men, under the command of Don Juan d'Aquila, were all that Philip of Spain would or could spare towards this effort to crush his rival, or at least to dismember her empire. To complete the series of ill-combined arrangements, the invading force landed at Kinsale, in the south of Ireland, whilst the ally whose interests it was sent to maintain was shut up in the northern extremity of the island. The Spaniards, as soon as they landed, were blocked up in Kinsale by the combined forces of the lord-deputy, and Sir George Carew, president of Munster. Don Juan wrote in the most urgent terms to O'Neill and O'Donnell to come to his relief. They advanced at the extraordinary speed of forty miles a day, through a country already desolated by the protracted continuance of a war of extermination. At the same time that they arrived near the scene of action, the landing of a second Spanish armament at Castlehaven, joined to the intelligence that this was to be followed by still further succours, induced several of the southern chieftains to declare themselves openly in favour of the Spaniards; and Mountjoy now found himself blocked up in turn, between the garrison of Kinsale on the one side and the Irish army on the other. Under such circumstances, delay would have been ruin. Famine and disease, already active in his camp, must soon have accomplished the annihilation of his army. The impatience of the Spanish general, and the want of concert among the Irish, saved him. O'Neill was prevailed upon to hazard an attack upon the English lines. In this he was anticipated. Mountjoy, aware of his intention, marched to meet him with part of his forces, leaving the remainder to keep the besieged in check. The enemy were taken by surprise, and, after a short resistance, the main body of the Irish was broken and scattered. O'Donnell, who commanded the rear, fled without striking a blow. O'Neill, after some ineffectual attempts to rally his men, still much superior in numbers, gave up the attempt in despair, and hurried back to the north. The Spanish general, finding himself deserted, and, as he thought, betrayed, by his new auxiliaries, surrendered upon terms. The war of desolation was now carried into the northern province. The forts of Charlemont and Mountjoy were erected to curb the Irish in that quarter. The open country was desolated. Large tracts were converted into deserts, where the miserable remnant of the population endeavoured to support nature by feeding on grass, or the filthiest garbage. O'Neill's friends and adherents gradually fell off. He at length applied to be received into mercy. Mountjoy, at this time aware of the precarious state of Elizabeth's existence, was equally anxious to terminate the struggle. After receiving from O'Neill an abject submission on his knees at Mellifont, he admitted him to pardon, and encouraged him with the hope of restoration to his title and estate. Scarcely had the ceremony been concluded when the news of Elizabeth's death arrived. O'Neill, on hearing of it, burst into a flood of tears, occasioned, as he said, by his regret for a princess whose kindness he had so ungratefully repaid, but, with more probability, by the reflection that an earlier intimation of the event might have enabled him to take advantage of it for procuring terms less degrading. The war could not have been much longer continued. It had worn itself out; the resources of the country were completely exhausted; the population was reduced to the number of from six to eight hundred thousand; the finances were in the most ruinous state; and the debasement of the coin, an expedient adopted by Elizabeth to parry off the ruin, ultimately served only to aggravate the distress.

With the exception of an effort made in the cities of Waterford and Cork to restore the old forms of worship, which was speedily put down with the effusion of but little blood, the submission of Tyrone restored the general tranquillity to such a degree, that Mountjoy felt justified in proceeding to England to present himself before his new sovereign, leaving Sir George Carew in his place as lord-deputy. He was accompanied by O'Neill and O'Donnell, the former of whom was confirmed in his title of Tyrone, and the latter created Earl of Tyrconnel. Before his departure he published a general amnesty, and received into the protection of the English law the whole of the Irish people hitherto exposed to the ill-defined rule of their respective chieftains. But the dawn of tranquillity was darkened by the apprehension of fresh convulsions. An anonymous letter was found in the council-chamber of the castle, hinting at the existence of a conspiracy carried on by some of the great Irish lords against the state. On the alarm being given, the Earls of Tyrone and Tyrconnel, actuated either by a consciousness of guilt, or by an apprehension that they were specially marked out as the objects of persecution, left the country, and took refuge in Spain. Their flight was considered as sufficient proof of their guilt. They were attainted, and their immense possessions forfeited to the crown. In one district of the north the flame of insurrection broke out openly. Sir Cahir O'Dogherty, proprietor of Innishowen, who had hitherto espoused the cause of the English, disclaimed his allegiance, seized by treachery the fort of Culmore, and thence proceeded to attack the town and fort of Derry, which he took by storm, putting the whole garrison, with the commandant, to the sword; but after continuing his ravages for five months, his followers were routed, and himself slain, in an engagement, by Sir Arthur Chichester, the lord-deputy, who found his presence necessary for the complete suppression of the insurrection.

The death of this chieftain and the flight of the two earls having placed nearly the whole of Ulster in the king's hands, he resolved to remodel the province, by removing the ancient possessors, and introducing a colony of English and Scotch settlers in their stead. The tract on which the experiment was to be made comprehended the counties of Tyrconnel, since called Donegal, Tyrone, Derry, Fermanagh, Armagh, and Cavan, spreading over upwards of half a million of acres. The lands were to be portioned out into estates varying from one to two thousand acres, the proprietors of which were bound to build substantial residences in them after the English fashion, and to people them with English and Scotch tenantry. The city of London was peculiarly active in promoting this plan. A company of merchants and undertakers there, under the name of the Irish Society, contracted for large tracts of land, which they still hold under this tenure. The remainder was portioned out amongst private individuals, either English or Scotch, who thus became the founders of most of the principal families now residing in these counties. The order of baronets was instituted in order to promote the execution of this favourite project of James. The number of its members was limited to two hundred, each of whom purchased his rank by the payment of a sum adequate to support thirty men on the new plantation for three years. About the same time, the county of Wicklow, heretofore the property of the septs of the O'Byrnes, and O'Tooles or O'Tothils, was made shire-ground, after the natives had been dispossessed by a summary process, somewhat similar to that employed in the settlement of the northern counties.

In order to secure the permanence of these changes by positive law, a parliament was convoked, after a lapse of twenty-seven years. It was the first to which members from all the counties of Ireland were sent. To secure a preponderance in favour of the crown, a number of new boroughs was created, in the charters of which the right of election was placed in hands which secured subserviency to the ruling power of the day. Notwithstanding this precaution, the political aspect which this assemblage presented was by no means promising. In the upper house, which consisted of but four earls, five viscounts, sixteen barons, and twenty-five bishops, the numbers of the latter order gave the crown an irresistible preponderance. But in the House of Commons the parties were more equally balanced. The election of a speaker served as a trial of strength. The court party proposed Sir John Davis, the attorney-general, an Englishman, and author of the celebrated tract on the Causes why Ireland had never been completely subdued. The country party set up Sir John Everard, an Irish lawyer of respectable family. The election went in favour of the former, by a majority of a hundred and twenty-seven votes to ninety-seven. The defeated party, not content with protesting against the unfair construction of the house, took advantage of the absence of the majority, who had left the apartment for the purpose of being counted on the division, put their own speaker in the chair, and were proceeding to pass resolutions, when the excluded members returned, and, failing in an attempt to eject Everard from the chair, placed their own nominee in his lap. The scene of disgraceful tumult which followed was at length terminated by the secession of the minority, after they had protested against all the acts that should be passed, as informal and unconstitutional.

A commission, issued for the discovery of defective titles, at the head of which was placed Sir William Parsons, a name of no small notoriety in the series of subsequent events, began now to excite alarm. During the long continuance of civil war, the loss of family documents, the neglect of the performance of feudal services, the ignorance of the great proprietors, and the uncertainty of the law fluctuating between English and Irish tenure, brought most persons of property within its fangs, and excited the alarm of all. By means of it the king established a claim of right to upwards of an additional half million of acres. The chief profit of these confiscations accrued to the members and dependents of the government, who employed agents, technically called discoverers, to scrutinize titles and discover flaws, receiving as their reward a portion of the lands charged with being concealed or illegally withheld from the crown. Their success in other parts led them to project the confiscation of the whole of Connaught. The king's claim rested on a case of the most flagrant iniquity. The lands of this province had been surrendered by their proprietors to Sir John Perrott, and restored to them by grants from the queen, to be held under the provisions of English law. Having neglected to enrol their patents in that reign of turbulence and internal commotion, they surrendered them anew to James, and took out new patents, for the enrolment of which a sum of three thousand pounds was paid. The officers of chancery, either through negligence, or from a worse motive, omitted to execute the process of enrolment, and the king, towards the close of his reign, was preparing to take advantage of the *laches* of his own servants, and to seize on Connaught, in order to have it parcelled out anew, as he had done with Ulster. The injured party, aware of their adversaries' power, prepared to avert the ruin which impended over them, by the proffer of ten thousand pounds. Whether the necessities of this extravagant monarch would have led him to the acceptance of that sum for the fulfilment of his part of an equitable contract, cannot now be decided. His death left the question at issue to be handed down to his successor, as one of the ingredients of discontent in the cup of bitterness that he was condemned to drain to the very dregs.

Charles I. began his reign by sending a large force to Ireland, both to provide against the danger of foreign invasion, and to curb internal disaffection; but, through a deficiency of pecuniary means to support the troops, he had recourse to the exertion of his prerogative, and quartered them on the counties and principal towns, obliging the inhabitants to supply them, not only with lodging, but with money and provisions. The murmurs against this oppressive impost were loud and frequent. A meeting of the principal Catholic recusants and great landed proprietors having assembled in Dublin, proposed to Lord Falkland, the lord-lieutenant, to grant the king a voluntary assessment of an hundred and twenty thousand pounds, on a guarantee of security in their rights and properties. The proposal was accepted by the king, who sent over the document containing the required concessions, ratified by his signature, in order to their being confirmed by the ensuing parliament. The principal articles in this covenant, which was known by the name of The Graces, were, that the king's claim to lands should be limited to sixty years; that the Connaught proprietors should receive new patents; that the exactions of the soldiery should be restrained, the fees of the king's officers and the powers of his courts defined, the powers of the ecclesiastical jurisdiction limited, and a general pardon granted for all past offences. When the parliament which was to give the sanction of law to these favours had met, an informality in the writs for assembling was alleged as a reason for not having then confirmed them; and as no new writs were issued, nor any steps taken to convoke another parliament, the people, who had advanced their money on the security of this promise, entertained strong doubts of the king's sincerity. The recall of Lord Falkland served to confirm these suspicions. The lords-justices who were appointed on his departure executed the laws against recusant Catholics with great severity. They caused the celebrated place of penance in Loughderg, called St Patrick's Purgatory, to be dug up and desecrated; and on being resisted by a tumultuous mob in an endeavour to prevent the Carmelite friars of Dublin from publicly performing their religious rites, they seized upon fifteen religious houses, and dispossessed the Catholics of their college in Backlane, giving it to the Dublin university, which kept it open for some time as a Protestant seminary. These measures only augmented the spirit of discontent, to repress which Charles sent over Lord Wentworth, afterwards Earl of Strafford. This nobleman, from being one of the most active leaders of the popular party in the English parliament, became at once the most violent assertor of the king's arbitrary measures. Equally proud and daring, he took no pains to conceal or palliate his desertion. "You see, gentlemen," said he to some of his former political friends, "I have quitted you." "We see you have," replied one of these sturdy republicans;

History.

"but, with God's blessing, we will never quit you while you have a head on your shoulders." His policy on his arrival was to treat Ireland as a conquered country, and to beat down opposition, from whatever quarter it might arise, by the stern arm of power. His arbitrary conduct made no distinction of persons. The Earl of Kildare having left the country without his permission, for the purpose of laying a complaint against his overbearing conduct before the king, was forced to make an abject submission to the person against whom he complained. Lord Mountnorris, for having used an unguarded expression, which could be distorted into a threat against the lord-lieutenant, was seized, tried by a court-martial, and sentenced to death, and escaped punishment only by the universal outcry raised against such a stretch of power. One Irish nobleman only had courage sufficient to oppose this conduct. Strafford, on the meeting of parliament, had issued orders that the members should lay aside their swords when they took their seats. The Earl of Ormond, who had just come of age, on being stopped at the entrance of the House of Lords, and required by the usher of the black rod to give up his sword, answered, that if that officer must have his sword, it should be through his body, and passed on to his seat. On being summoned before the council to answer for this daring insult on the viceregal authority, he defended himself by saying that he had received the investiture to his earldom *per cincturam gladii*, and was ordered by the writ of summons to attend parliament *gladio cinctus*. The answer, as spirited as it was unexpected, staggered Strafford. He felt that such a spirit in so young a man must either be crushed at once, or otherwise directed. He had the prudence to adopt the latter course; and Ormond, at the age of twenty-four, was admitted into the Irish privy council. The imperious and harsh measures of the lord-lieutenant had, however, the effect of putting down all opposition in parliament. Six subsidies, amounting to three hundred thousand pounds, were granted, and no steps taken to secure to the people, by the sanction of parliament, those graces which the king had pledged himself to grant, and for which they had paid so highly. In some respects Strafford's government was laudable. He reformed the army, so as to render it efficient without being burdensome to the people; he encouraged the linen manufacture, using at the same time every means to depress that of wool; he promoted a spirit of commerce, and guarded the coasts with great vigilance against the annoyance of pirates. Amongst the worst acts of his government, was his project to subvert all titles to estates in Connaught, in order to plant a new Protestant colony in that province. Taking with him a large body of soldiers to overawe the juries, he held courts of inquest to investigate titles. His measures were effectual in four counties. In Galway, the jurors having presumed to give a verdict against the crown, were summoned before the court of the council chamber in Dublin, and the sheriff fined a thousand pounds for returning an improper jury. The exigencies of Charles's affairs induced him to call over Strafford to England, where, after some time, he was impeached by the House of Commons. The principal charges against him rested upon his conduct whilst in Ireland. Several articles were certainly groundless, others exaggerated, but more than sufficient remained to justify the sentence which brought his head to the block, and fulfilled the ominous prediction of the party he had deserted when in the zenith of his prosperity.

Whilst general discontent in Ireland was fermenting through the duplicity of the king, the arbitrary conduct of his officers, the suggestions of his enemies in England, and their bloody triumph over his great agent, a secret conspiracy was forming to rescue the country by force of arms from its present oppressed state, and to restore the property of it to those whom the late changes had ejected. The deviser and main-spring of the plot was Roger Moore, a descendant of the O'Mores of Leix, who had been dispossessed in the reign of Mary. In conjunction with a son of the Earl of Tyrone, who, on escaping to Spain, had obtained the command of a regiment in the Spanish service, he set about procuring the means to accomplish this daring measure. Returning to Ireland, he gained over several of the heads of the old Irish families. The death of Tyrone checked, but did not prevent, his proceedings. Application was made to another branch of the family, Owen Roe O'Neill, then in the service of the king of France, from whom the conspirators received assurances of military aid when matters should be ripe. The seizure of the castle of Dublin was to be the first overt act, and the 5th of October was fixed on for the attempt. The timidity of some of the parties caused its postponement. Roger Moore, after having visited his friends in Ulster, on whose exertions, owing to the severity with which they had been dispossessed in the late settlement of that province, he placed most dependence, came up to Dublin to superintend the attack, which was now fixed on for the 23d of the same month. The lords-justices, Sir William Parsons and Sir John Borlase, were till this moment unaware of the conspiracy, and unprepared for resistance. On the evening of the 22d, information of its existence was given, through Owen Conolly, a Protestant, who had been invited to join in it. Parsons paid little attention to his statement, but Borlase took the alarm, placed guards on the castle and principal avenues, and seized M'Mahon and Lord M'Guire. Moore had sufficient notice of the discovery to make his escape. Dublin was thus saved; but the insurrection broke out with irresistible fury in the north, where Sir Phelim O'Neill, one of the Tyrone family, a man of mean capacity but violent passions, took the lead, by surprising the castles of Charlemont, Dungannon, and Mountjoy. Tanderagee, and the border town of Newry, soon afterwards fell into the hands of the insurgents. Fermanagh was seized upon by a brother of Lord M'Guire, and Monaghan by the M'Mahons. So well organized was the conspiracy, that within eight days' time the Irish found themselves masters of the counties of Tyrone, Monaghan, Longford, Leitrim, Fermanagh, Cavan, Donegal, and Derry, together with some parts of Armagh and Down.

In the mean time the lords-justices were engaged in taking measures for their own security in Dublin. All strangers were ordered to quit the city. Parliament was prorogued. The sheriffs of the counties of the pale received orders to provide for the security of their respective districts. The Catholic lords of the pale attended the counsel, declaring their readiness to assist in the defence of the country. The lords-justices, suspicious of their motives, yet unwilling to irritate them by an expression of doubt, furnished a small supply of arms to those most exposed to danger. After the first burst of an explosion so general and so unexpected, the progress of the insurgents failed to keep pace with their primary exertions. The Protestants in Down took refuge in Carrickfergus. In Fermanagh, Enniskillen set the attempts of the insurgents at defiance, and Lord M'Guire's castle was taken by storm. Sir Phelim O'Neill was driven with disgrace and loss from Castlederg, was defeated in Donegal, forced to retire from before Newry, and again routed at Lisburn, then called Lisnegarvey, with such slaughter that the number of the slain is said to have trebled that of the garrison. These reverses were attended with consequences truly dreadful. The Irish, exasperated by defeat, carried on their hostilities without mercy. The inhabitants of Lurgan, who had surrendered on terms, were seized, and the town plundered. Lord Caulfield, who had been taken in Charlemont, was murdered, with fifty others. Prisoners, whilst removing from one place of confinement to another, were attacked on the road and massacred, or driven into the nearest river. These excesses were not confined to the one side only. The garrison of Carrickfergus fell upon the Catholic inhabitants of the neighbouring peninsula of Island Magee, and forced a number of them over the rocks into the sea. Sir Charles Coote, who was sent out from Dublin to oppose the insurgents, carried on a war of extermination against all suspected of favouring them. That these atrocities did not stain the rebellion at its commencement, but grew out of its progress, is evident from the fact, that no mention of a massacre is made in any of the proclamations issued by the lords-justices, even so late as the 23d of December, three months after its commencement; the protestation of the Irish parliament, which met on the 17th of November, is also silent on the point; nor does any state paper emanating from the Irish government afford grounds for the charge. The parliament, on assembling, sat but for two days. Its only acts were a protestation against those who had taken arms, and the appointment of a committee to confer with their leaders. Alarmed at this act of concession, it was prorogued by the lords-justices; and the conference was broken off in the most indignant manner by O'Moore, when he found himself and his friends stigmatized in it by the name of rebels. The lords-justices now proceeded to deprive these noblemen and gentlemen of the pale of the arms furnished to them in the first paroxysm of terror. Exposed thus undefended to the attacks of the insurgents on the one hand, and to the suspicions of the government on the other, they held meetings with the leaders of the insurrection, first at the hill of Crofty, and afterwards at that of Tarah, in consequence of which they determined to embody themselves as a force distinct from the Ulster Irish, under the command of Lord Gormanstown and the Earl of Fingal, with the professed purpose of confining their operations to self-defence. The lords-justices were alarmed. They now sent to invite the discontented lords and gentry to Dublin, to confer with them on the state of the country. These excused themselves, on the plea that they would not venture within a city under the control of Sir Charles Coote, whose sanguinary speeches at the council board, and massacres throughout the country, had already rendered him peculiarly obnoxious. They also drew up an address to the king, complaining of the injurious conduct of the lords-justices, by which they had been driven to the necessity of arming themselves in their own defence; and they published a manifesto to the same purport, for general circulation. The latter document produced a decisive effect. The insurrection, hitherto confined to Ulster and a small portion of Leinster and Connaught, at once became general. At the commencement of the year the authority of the lords-justices was confined to Dublin and Drogheda, the latter of which was in a state of siege. In Connaught, the town of Galway was retained in its allegiance through the influence of the Marquis of Clanricarde, the king's steady friend. In Munster, the cruelties of Sir Warham St Leger, president of the province, which equalled those of Sir Charles Coote in Leinster, drove even those hitherto well disposed into insurrection.

The arrival of supplies of men from England produced a change, and encouraged the lords-justices to exert themselves to crush their enemies. The means adopted by them were those of extreme severity. The prisoners of the lower orders brought into Dublin were summarily executed by martial law; those possessed of lands were tried by the regular course of law, in order to secure the confiscation of their property. Bills of indictment for high treason were found against all the Catholic nobility and gentry in Meath, Wicklow, and Dublin, and against many in Kildare. Several persons of imputed guilt were put to the torture to extort confessions. The Earl of Ormond, who had the command of the army, received instructions not only to kill all rebels and their adherents, but to burn all the places where they had been harboured, and to destroy all the male inhabitants capable of bearing arms. Nor were these merely denunciations, circulated for the purpose of producing obedience through terror. Sir William Cole's regiment alone boasted, that, besides killing two thousand five hundred men in battle, they had starved and famished, of the vulgar sort, whose goods they seized on, seven thousand. The Earl of Ormond was despatched into the county of Kildare to relieve and secure the castles which still held out for the government. After executing his commission, he defeated at Kilrush a large body of the Irish under Lord Mountgarret; but being unable, through want of supplies, to follow up his advantage, he was forced to content himself by thus securing a safe retreat to Dublin.

On the other side, the arrival of Owen Roe O'Neill gave fresh vigour to the cause of the Irish in Ulster. A Scotch force, which had been sent thither under the command of Lord Leven, remained inactive. Lord Leven, after an empty display, quitted the country, leaving the command to General Munroe, who, following the example of his predecessor, remained quiet in his quarters, whilst the forces of O'Neill were daily augmenting, by the accession of numbers of the natives, and by supplies of officers, military stores, and money, from the Continent.

The insurgents now began to find themselves sufficiently powerful to give form and regularity to their proceedings. A general assembly of delegates from all the provinces was convened at Kilkenny. Their first act was a declaration, in which, after professing their determination to adhere to their allegiance to the king, they disclaimed the authority of the Irish government in Dublin, administered as it was by a malignant party in conjunction with the king's enemies in England. They appointed for the execution of their edicts subordinate councils in the provinces, from which there was to be an appeal to the supreme council of the Catholics of Ireland, a permanent body, consisting of twenty-four members, chosen by the general assembly. Having thus organized their civil constitution, they provided for their military operations by giving Owen Roe O'Neill the command of their forces in Ulster; General Preston, who had lately brought a supply of arms and ammunition from France, in Leinster; Garret Barry in Munster; and Colonel Burke in Connaught. Lord Castlehaven, who, on the first breaking out of the war, had made a tender of his services to the government, but had been refused, having afterwards appeared in Dublin to justify himself from a charge of treason, was thrown into prison, whence he contrived to escape after a confinement of twenty weeks, and was appointed to the command of the Leinster cavalry.

The good effects of system soon showed themselves. Munroe was defeated in Ulster, and the united forces of Lords Muskerry and Castlehaven were successful in Munster. Connaught was wholly in obedience to the confederates; and though Preston had allowed himself to be defeated near New Ross, Lord Ormond found himself too weak to reap any decisive advantage from his victory. Yet, notwithstanding these favourable appearances, the leaders of the confederates, aware of the great superiority of their opponents, and not firmly united amongst themselves, were anxious to put an end to hostilities. But the English parliament obstinately refused to negotiate with those whom they styled rebels and murderers. The Earl of Ormond at the same time undertook to continue the war on the part of the crown, provided the lords-justices furnished

History.

him with a supply of ten thousand pounds. After much delay, a cessation of arms was acquiesced in by both the belligerent parties, for which the confederates agreed to advance to the amount of thirty thousand pounds for the king's service, one half in money, and the remainder in cattle.

The great object of the cessation of hostilities was to procure from the king a permanent settlement of the country. Both parties sent in their proposals. In these the Catholics asked for freedom of religion, seminaries for the education of their children, a free parliament, from which all who had not property in Ireland should be excluded, and an amnesty for the past. The Protestants, on the contrary, called for the strict execution of the penal laws, the total disarming of the Catholics, the vesting of all estates hitherto forfeited in the crown, and the distribution of them when so vested amongst English settlers exclusively. Charles gave no decisive answer to any of these proposals. He pleaded the difficulties of his situation, and referred them to Ormond, whom he had appointed chief governor instead of Parsons and Borlase, and had raised to the dignity of a marquis. Ormond procrastinated. The mean motives of avarice and personal aggrandizement are charged against him for his indecision in such an emergency. But be the cause what it might, the opportunity for a pacific settlement was let slip, and lost for ever.

The first eventful change was the desertion of the confederate party by Lord Inchiquin, who, on being refused the office of president of Munster by the king, declared for the parliament, and became the bitter enemy of his former associates. Still, however, the confederates had the advantage in several minor encounters, for military operations were not wholly stopped by the armistice. At this period, whilst they refused to furnish the king with supplies either of men or money until their interests were more fully secured than by the temporary stipulations of a truce, and whilst Ormond, on the king's part, resisted every attempt at a permanent peace, the pope's legate, Rinuncini, archbishop of Fermo, arrived, and in his master's name protested against any pacification which did not secure the public establishment of his religion. Charles, pressed by the exigencies of his situation, and unable to overcome Ormond's reluctance, employed another agent. He sent over the son of the Marquis of Worcester, Edward Lord Herbert, better known by the title of Earl of Glamorgan, to which he was soon afterwards promoted, who, through his influence with the confederates, succeeded in persuading them to make a double treaty, the one public, the other private; which latter contained articles insisted on by the Catholics, but deemed to be such as, if generally known, would increase the prejudice against the royal cause in the minds of the English. The secret clauses were, a provision that the members of each religious persuasion should pay their tithes to their own clergy, and that the churches should remain in the hands of their present possessors.

Rinuncini, who, while on his way to Ireland, had obtained from the queen an assurance of terms even more favourable than those of the private treaty, objected to both of them; he also insisted on the publication of the former. His wish was accomplished by an accident. Sir Charles Coote, the second of the name, for the former had been killed in a skirmish soon after the breaking out of the war, having defeated, near Sligo, a body of men commanded by the Archbishop of Tuam, found amongst the baggage of this prelate a copy of the secret articles. The document was immediately transmitted to the English parliament, which lost no time in publishing it throughout all parts of the country. Charles at once denied its authenticity. He declared that Glamorgan had exceeded his powers, and caused him to be arrested on a charge of treason, and examined before the Irish privy council. His duplicity gained him but little credit even at the time, and documents preserved in the public libraries of England have since furnished incontestible proofs of his insincerity. Glamorgan was soon liberated upon bail. The transaction destroyed all remaining confidence between the confederates and the king. Ormond refused to ratify the secret articles. Rinuncini, also, who had private information of the progress of a treaty at Paris between Charles and the pope, insisted on delay. In the mean time, the king's affairs became desperate; and Ormond, when it was now too late, consented to relinquish his objections to the repeal of the penal laws, and concluded a treaty with the confederates. But the want of confidence excited by the king's conduct caused delays in carrying the terms of the treaty into effect, which ended in the utter ruin of the royal cause. Rinuncini, still averse to a compromise which withheld from the Catholic church the enjoyment of any of its former privileges, made party with Owen Roe O'Neill, who, through the aid of the nuncio's money, was enabled to undertake offensive operations, and defeated Munroe at Benburb, a village on the Blackwater. Rinuncini, elated with his success, entered Kilkenny, appointed a new confederate council, and imprisoned the members of the old one. Ormond, in despair, resigned the sword of state, and retired to the Continent; and though he returned again armed with full powers as lord-lieutenant, and though a new general assembly of the confederates, convoked at Kilkenny, had declared themselves favourable to terms in which both parties might be led to acquiesce, and were violent in their protestations against the stubborn resistance of the nuncio, the adoption of any decisive measure was postponed, until all were aroused from their lethargy by the appalling news of the demand made by the parliamentary army in England to bring the king to trial. Then, indeed, the confederates agreed to the terms proposed by Ormond. The leading points were, the free exercise of religion, and the retaining of the churches then in possession of the Catholics until the king's pleasure should be known. Twelve individuals appointed by the general assembly, under the name of the commissioners of trust, were made guardians of the treaty, and vested with powers to levy soldiers, raise money, and perform all acts of supreme authority. The treaty was signed on the 17th of January 1648. But it was then too late. Before the news of its ratification could arrive in London, Charles had forfeited his life upon the scaffold.

Previously to the death of the king, no less than five armies were maintained in Ireland, each acting for a different object. The Marquis of Ormond commanded that of the king, for the purpose of restoring him to his government. The parliamentary forces, under Colonel Jones, had possession of Dublin; and in the south he was supported for some time by a force under the Earl of Inchiquin. General Preston commanded the troops of the confederate Catholics in Leinster. Owen Roe O'Neill, who had attached himself to the nuncio, and therefore was equally opposed to the king, the parliament, and the confederates, had the command of all Ulster, except a small portion of its eastern extremity, where Munroe was at the head of an army which favoured the Scotch. All these elements of intestine commotion were again thrown into action by the king's death. Rinuncini, indeed, finding that this event, which he was charged with having hastened by his obstinacy and violence, had alienated the whole of the Catholic population, quitted the country privately. Ormond then endeavoured to gain over O'Neill, but failed; he afterwards made overtures to Colonel Jones, with whom he was equally unsuccessful, his proposals being met with the retort that his suspicious conduct had been the cause of exciting the apprehensions of the king's insincerity, which prevented any of the parties in Ireland from coalescing with him sincerely, and thus led to his destruction. Having at length, from his own resources, collected an army sufficient to take the field, he invested Dublin, with the intention of reducing it by famine. But an advanced post at Baggotsrath having been successfully assaulted by a sortie from the garrison, which followed up its success by an attack on the marquis's head-quarters at Rathmines, the whole besieging army was seized with such an unaccountable panic that it dispersed in all directions, leaving the general so utterly deserted, that when he wrote to Jones respecting the prisoners who had fallen into his hands, this officer's taunting reply was, that he did not know where to find his lordship in order to wait upon him on the business.

Before the marquis could recover from the effect of this defeat, news was brought him of the arrival of Oliver Cromwell in Dublin, with a select and well-appointed army of ten thousand men. After a short delay in that city to refresh his troops and to regulate the civil affairs of the country, Cromwell proceeded to besiege Drogheda, which Ormond, suspecting his intention, had provided with a good garrison, and abundance of military stores. After having made a practicable breach, the assault was given, but the besiegers were twice repulsed. On the third attack, led on by Cromwell in person, his troops forced their way into the town, and the garrison laid down their arms on promise of quarter. The promise, however, was kept only as long as resistance was apprehended; for as soon as the place was completely reduced, orders were issued for the indiscriminate massacre of the inhabitants, without distinction of age or sex; which were so punctually obeyed, that thirty only survived, who were forthwith transported as slaves to Barbadoes. From Drogheda Cromwell proceeded southwards to Wexford, which being well garrisoned and provided, was expected to make a long resistance, so as to give time to Ormond to collect his forces from other quarters. But it was betrayed by the treachery of the officer placed in command of the castle, and, when taken, treated with the same merciless cruelty as that which had before marked Cromwell's triumph at Drogheda.

The effect of these terrible examples of severity in paralyzing opposition, was increased by the orders given by Cromwell to his troops to abstain from any wanton injuries on the peaceable peasantry, and to pay them in full for all their supplies; a system directly contrary to all former practice, according to which, the soldier, whether friend or foe, was ever the peasant's terror.

The only hope for the royalist party now rested in the cordial union of Ormond and O'Neill. Both were sensible that a junction of their forces was absolutely requisite to counteract the movements of Cromwell. To effect this object, O'Neill moved southwards with his army, but was seized on his march with a defluxion of the knees; a complaint attributed at the time to a pair of poisoned boots prepared for him by an agent of the confederates. Unwilling to retard the movements of the armies, he had himself conveyed in a litter, but sunk under the accumulated pressure of disease and fatigue, and died at Clough-outer Castle.

The commissioners of trust were so much alarmed at the treatment of Drogheda and Wexford, that they were with difficulty prevented, by the remonstrances of Ormond, from abandoning Kilkenny. The want of confidence which he experienced, both from the leaders of the confederates, and the inhabitants of several of the large towns in the south, tended much to embarrass him. The city of Waterford absolutely refused admission to his troops, even at a time when a passage through it was required to make a successful assault on the retiring army of Cromwell. This general commenced the campaign in 1650 by a movement on Kilkenny, which was to have been betrayed into his hands. But the plot being discovered, and the traitor executed, he was forced to lay regular siege to the place. It made a very gallant defence. After a breach had been effected, the besiegers were repulsed in two attempts, and Cromwell was preparing to retire, when he received secret information that the town magistrates were anxious to surrender. A third assault was then made, with as little success as the former; but Ireton having come up with a fresh supply of men, and the garrison having been informed that no assistance could be afforded them from without, the town surrendered on terms highly honourable to its defenders, who, on marching out, were complimented by Cromwell for their gallantry, and told, that had it not been for the treachery of the town's people, he must have raised the siege.

Clonmell still held out against the parliamentary army. The garrison was commanded by Hugh O'Neill, another branch of the family which had signalised itself in the wars of Ireland. The first assault was repelled with such slaughter that the infantry refused to advance a second time, and Cromwell was compelled to bring forward his own favourite regiment of cavalry. These succeeded in entering the breach, but met with an opposition so fierce and so unexpected, at a retrenchment thrown up within, that the greater part of the storming party lay dead or wounded on the spot, and the remainder evacuated the place. In the two assaults Cromwell lost two thousand of his best soldiers. Not daring to venture on a third, he changed the siege into a blockade. The Marquis of Ormond, aware of the importance of the place, made every exertion for its relief. Assisted by the Catholic bishop of Ross, he collected a numerous but tumultuary body of men in the western part of Cork. These were attacked and routed, and the bishop taken. His life was promised to him, provided he would prevail on the garrison of a neighbouring fort, which greatly annoyed the besiegers, to surrender. On going thither, he exhorted the garrison to persevere in their defence, and, on his return to the camp of Cromwell, was executed. O'Neill having defended the town as long as his ammunition lasted, withdrew his troops by night unobserved; and Cromwell, unaware of the movement, gave the people very favourable conditions, to which he was the more inclined, as the intelligence of Charles II. having taken refuge in Scotland, and the hostile indications from that quarter, rendered his presence in England necessary to his party. Immediately after the surrender of Clonmell, he proceeded to Youghal and embarked for England, leaving the army in charge of his son-in-law, Ireton.

All rational hope of successful resistance to the parliament was now at an end. Ormond prepared to quit the kingdom. The commissioners of trust for some time opposed his intention, conscious of the confusion which must arise from such a public avowal of his despondency. But with the Catholic clergy it was otherwise. They suspected that he was secretly negotiating with Cromwell. His former conduct afforded plausible grounds for such a suspicion; and during the siege of Clonmell he had procured passes from that general for himself and Lord Inchiquin to go to England. A synod of the bishops, held at Jamestown, resolved upon sending a deputation to him, calling upon him to quit the country, and transfer his powers to some trustworthy person, who enjoyed the confidence of the nation. A second resolution denounced excommunication against all who should hereafter adhere to him. Whilst the relics of those who professed attachment to the royal cause were wasting their strength and ruining their prospects by these proceedings, Ireton was engaged in extending his authority by the reduction of

History.

one place of strength after another. Ormond, as a last resource, convened a general assembly at Loughrea; but the party of the clergy was too powerful. Finding all means ineffectual to induce them to recall their hostile declaration, he embarked in a frigate provided for him by the Duke of York, transferring his powers as lord-lieutenant to the Marquis of Clanricarde. An extraordinary negotiation was now commenced with the Duke of Lorraine, by which it was proposed, that on the advance of a large sum of money, and a proportionate supply of military stores, he should be declared protector of the royal cause, and receive some towns as cautionary securities. But the rapid progress of Ireton baffled all these projects. Limerick was reduced, partly by the effects of a pestilential disease, partly by treachery. Amongst the victims of the plague was Ireton himself. After his death, Galway surrendered to Ludlow, his successor. A last desperate attempt at resistance was made in Connaught by Clanricarde, aided by Sir Phelim O'Neill, who now again began to make himself conspicuous. It was defeated, and Clanricarde fled to one of the islands on the coast. Sir Phelim was taken prisoner, and ultimately executed as a traitor. The nuncio's party sent ambassadors to offer the crown of Ireland to the pope, the kings of France and Spain, and the Duke of Lorraine; but none of them would accept the worthless bauble. Clanricarde still endeavoured to maintain a mountain war amidst the glens and wastes of western Connaught. It was but the expiring effort of unbending loyalty. At length a letter from Charles, recommending him to provide for his own safety, released him from the shackles of the self-imposed bonds of loyalty. He applied to Fleetwood, Cromwell's deputy, for a pass to retire to England. It was granted, and he submitted to the parliament on an assurance of not being called upon to perform any act inconsistent with his duty to his sovereign. Shortly afterwards, a proclamation from the English parliament announced the termination of what was called the rebellion in Ireland.

The victors had now only to share the spoil. The greater part of the nobility and gentry of Ireland, and of the army, had expatriated themselves; the estates of the confederates were deserted. It remained to apportion them amongst the friends and followers of the parliament, in such a manner as would best secure a zealous attachment to the new order of things. The ordinance of the English parliament to this effect decreed, that all who had been concerned in the rebellion previously to the 10th of November 1641, all Jesuits and priests, all who, not being themselves in arms, had slain English soldiers, and all who, being now in arms, did not lay them down within twenty-eight days, should be excepted from pardon. The Marquis of Ormond, the Earls of Inchiquin and Roscommon, and Bramhall, Protestant bishop of Derry, were also specially excepted. All persons who had borne a command against the parliament were to be banished during pleasure, to forfeit two thirds of their estates, and to be assigned lands to the value of the remaining third wherever the parliament should appoint. All Catholics who had resided in Ireland at any time during the war, and had not manifested their constant good will to the commonwealth of England, were to forfeit one third of their estates. All others residing in Ireland, as before, who had not been in arms for the parliament, or manifested their good will towards it when an opportunity offered, were to forfeit one fifth.

A high court of justice, somewhat of the nature of a court-martial, being composed of parliamentary officers, who acted in the double capacity of judges and jurors, and whose decisions were not regulated by any settled rules of evidence, sat on the cases of delinquency. Yet, after the severest scrutiny, the number of those subjected to the penalties of the first clause of the instructions was very small. Lord Mayo in Connaught, and Colonel Bagnal in Munster, were condemned, as it was thought, unjustly. Lord Muskerry was saved by the evidence of the numerous English settlers, who pressed forward to vouch for the protection and security they enjoyed under his control. In Ulster, Sir Phelim O'Neill was the only victim. Although offered not only pardon, but restoration of property, if he could produce substantial proof that he had had a commission from Charles to commence the insurrection, he disclaimed the fact, and died maintaining the contrary. Of others, not quite two hundred could be found who came within the strictness of the clause, so much had the accounts of the atrocities committed at the breaking out of the insurrection been magnified, or so completely had the actors in it been swept off by the desolation of the hostilities that succeeded.

The disposal of the forfeited lands was regulated according to the principles of an act of the English parliament, by which those who at the commencement of the war had subscribed L.200 towards the reduction of Ireland were to have 1000 acres in Ulster; those who had subscribed L.300, the same number in Connaught; and those who had subscribed L.450 and L.600, a like quantity of land in Munster and Leinster. The holder of the lands thus granted was bound to pay a yearly quit-rent to the crown, of one penny an acre in Ulster, three halfpence in Connaught, two pence in Munster, and three pence in Leinster. The soldiers who had served in Ireland since the landing of Cromwell there in 1649, were entitled to a share of the lands in lieu of their arrears, on the same terms as those who had advanced money, and who were distinguished by the name of adventurers. Those who had served previously to that date were to look for payment to the residue of lands which might be over and above after the former division had been made; a kind of security which was found to be very deficient. In order the more effectually to secure the new possessors in their properties, the Catholics who should be found entitled to retain any part of their estates under the provisions of the act above specified, were to surrender such part if in any of the other provinces, and to receive an equivalent, or, as it was called, "to be reprized," by waste lands in Connaught, which new allotments were assigned in the parts of the province situated at least a mile from the coast. No Catholic was, under any condition, to be suffered to remain in a town, or within a certain space around it. By the latter part of this provision, it was intended to cut off the Irish from any communication with foreigners, as by the former the broad boundary of the Shannon separated them from any contact with the residents in other parts of the kingdom. Commissioners of delinquency sat at Athlone, to decide upon the qualifications of the Roman Catholics; others, appointed to arrange the details of settlement of those transplanted to Connaught, held their court at Loughrea. A third body of commissioners met in Dublin, to receive and hear claims. Under their direction a survey was made by the celebrated Sir William Petty, of all the forfeited lands, which, notwithstanding the lapse of time, and the state of the country when executed, is found to be singularly correct in its details. The confiscation comprehended by much the greater part of the surface of Ireland, and threw the property, and consequently the influence, of the country into the hands of a new class of men. Private soldiers, or desperate adventurers, now became the lords of extensive tracts, once enjoyed by the native families of ancient descent, or by the Anglo-Irish nobility. It also produced another change, of less striking character at first, but of overpowering influence on the future destinies of the country. The land was likely to be useless for want of cultivators. The continuance of a warfare, in which mercy was deemed a symptom of timidity or

History. of treachery, had swept away the peasantry in multitudes. Numbers had been transported as slaves to the plantations; many had emigrated as soldiers or colonists. The plan of peopling the wilds of Connaught by transplanted Catholics was almost totally relinquished. Hands were wanting on the new estates; the tenants were therefore retained, but they were treated with all the jealous severity arising from a consciousness of weakness, and an apprehension that advantage would be taken of it. They experienced the harshness of slavery, without the enjoyment of that protection which the selfishness of ownership in some degree spreads over it.

The government of Ireland was intrusted by Cromwell to his son Henry, who proved himself worthy of the choice. He visited most parts of the island, so as to make himself personally acquainted with its resources and capabilities. He checked the frauds attempted to be committed by the commissioners in the disposal of the forfeited lands, repressed the violence of the soldiery, and afforded the protection of the law to the ill-used peasantry. He had even devised plans on an extended scale for the improvement of the country, which the short duration of his power prevented him from executing. Impressed with the necessity of diffusing knowledge as the surest foundation for the solid advancement of the people, he purchased the library of Archbishop Usher, in order to bestow it on a second college which it was intended to found in Dublin. Amongst other plans for the consolidation of the interests of the two countries, it was intended that Ireland, instead of being governed by a domestic parliament, should send representatives to that of England. The number fixed upon was thirty. But the death of Cromwell, and the resignation of his son Richard, put an end to all these well-intended projects. On the announcement of this latter event, the English parliament, aware of Henry Cromwell's abilities and popularity, and apprehensive of an attempt on his part to maintain himself in the government, sent over Sir Hardress Waller to seize upon the castle of Dublin; but the precaution was unnecessary. Cromwell retired without opposition, remaining in privacy in his house in the Phœnix Park until he had provided himself with the means of removing to England, having administered the government with so much disinterestedness during a period in which he had the means of amassing unlimited wealth, that he could not at once defray the expenses of his passage over.

The thoughts of the new settlers, who were now transformed from needy adventurers and soldiers into landed proprietors, began to turn upon the means of securing the properties so unexpectedly acquired. The agitation consequent on the death of Cromwell, whose overruling master-mind had hitherto kept all parties subservient to his views, began to take a turn decidedly favourable to the restoration of royalty. The great leaders of the parliamentary party perceived this, and prepared to shape their course accordingly. Lord Broghill, who had already changed from a royalist to a republican, was the first to retrace his steps. He was followed by Sir Charles Coote, the most sanguinary of the parliamentary leaders. The towns of Youghal, Bandon, and Kinsale, which had been amongst the first to revolt to Cromwell, were now led by Lord Broghill to declare for the king. Coote secured Galway and Athlone. The same party, after a short struggle, seized upon Dublin Castle. Sir Hardress Waller, who had taken possession of it for the parliament, was sent a prisoner to London; and Ludlow, who, upon the alarm of the change of sentiment in the parliamentary party in Ireland, had been sent over to take the chief command, on arriving in Dublin Bay, was prevented from landing, and forced to return to England. A convention was assembled in Dublin. The council of state in England ordered its dissolution. The order was set at defiance. The king's declaration at Breda being presented to the convention, was accepted by acclamation, and Charles was proclaimed with every demonstration of joy in all the great towns. Thus, the restoration of the son in Ireland was effected by the same persons who had been mainly instrumental in bringing his father to the block.

The sudden change of public opinion gave Charles irresistible influence in Ireland. All parties looked to him. Above all, the Catholics, whose attachment to his father had been the great cause of their sufferings, and of the ruin of their property, anticipated an immediate restoration of their estates. So sanguine were they, that many proceeded to take forcible possession of them, and to eject the new proprietors. The Protestants raised the cry of a new rebellion, employed agents in London to resist their claims, and had influence sufficient to obtain clauses in the act of indemnity, excluding from it all who had at any time aided the Irish, and prohibiting the restoration, upon any terms, of lands already disposed of by the parliament or convention. Nor was it without the greatest difficulty that an exception could be carried in favour of the Marquis of Ormond and other Protestants. Every severe ordinance against the Catholics was strictly enforced. The commoner sort were prohibited from quitting their place of residence without permission. Assemblies of the Catholic gentry were forbidden. A proclamation was issued for apprehending Irish rebels, and for assuring all adventurers and soldiers in the quiet possession of their grants.

At length the king's declaration, which was to form the basis of the new settlement of the landed property of the country, was published. This document, after vesting all the confiscated property in the king, confirmed the adventurers and soldiers in the lands already granted to them. The officers in the king's service before 1649, distinguished by the name of "Forty-nine Men," were to receive their arrears in lands at the rate of twelve and sixpence in the pound, and an equal dividend of whatever should remain of their security. Protestants whose estates had been given to adventurers were to be restored, and the present holders "reprised," that is, given other lands of equal value. Innocent Papists were also to be restored, and the holders reprised; those restored to property within corporate towns were to be reprised in the neighbourhood, as no resident Catholics were to be permitted in those places. Such Catholics as had accepted lands in Connaught were to continue bound by that act. Those who had joined the king in his exile, and served under his banners, were to be restored when the present holders were reprised; such persons were called "Ensign-men." Additional grants were made to Ormond and Inchiquin, who had been restored by the English parliament. Monk, now Duke of Albemarle, and some others, received grants. The king's brother, James, duke of York, had several of very great extent. Thirty-six of the Irish nobility and gentry, to be specially named by the king, were also to be restored under the title of "Nominees." Those who had any share in the trial and execution of the late king were specially excluded from the benefit of this arrangement. Lands belonging to corporations were to be restored, and the possessors reprised. The qualifications which entitled a Roman Catholic to claim the benefit of the clause respecting "innocent Papists," were so worded as to render the chances of an acquittal almost impossible. None were to be restored as such, who, at the time of the cessation in 1643, had been of the royal party, or had lived within the quarters of the confederates, except the inhabitants of Cork and Youghal, who had been forcibly expelled from those towns, and driven by the fanatics into the enemy's lines; who had acted with the confederates before the peace of 1648, or had adhered to the nuncio or the papal power against the royal authority, or, when excommunicated for such adherence, had submitted and obtained absolution. Whoever derived his title from persons guilty of those crimes; whoever claimed his estate on the articles of peace, thus acknowledging his concurrence in the rebellion; whoever had held correspondence with the confederates, sat in their councils, or acted under their commission; whoever had employed agents to treat with any foreign power to bring forces into Ireland, or had been a tory, the name given to the marauding parties which harassed the country; were also excepted. Few Roman Catholics could hope to escape being included in some one or other of those sweeping clauses.

The principal subjects which engaged the attention of the Irish parliament that met after the Restoration, were the established church, and the settlement of property. Ormond, to whom the management of Irish affairs was principally intrusted, contrived, by postponing the consideration of the question of the lands, to secure the adoption of the former. Although the House of Commons was almost exclusively composed of those who had a few years before been most zealous in pulling down the church and abolishing the liturgy, it now not only readily assented to the revival of both, but concurred in censuring the solemn league and covenant, and in condemning their former oaths of association. They also procured an order from the lords-justices to adjourn the law term, and close the courts of justice, in order to prevent the reversal of outlawries, or the ejectment of adventurers and soldiers before their titles could be secured by statute.

The act of settlement, the next object of parliamentary attention, was framed according to the spirit, and nearly according to the letter, of the declaration published by the king. The principal alterations were respecting reprisals, and what was called the doubling ordinance. The commissioners of the court of claims had been guilty of gross partiality respecting these. They rejected the claims of the nominees, and the ensign-men, on the plea that there were not lands sufficient to reprise the present possessors, a defalcation caused by the clandestine disposal by themselves of these lands to their own friends. Through the exertions of the House of Lords, a clause was inserted for the revocation of these fraudulent grants. The doubling ordinance was still more pregnant with injustice. The English parliament having found that the sums subscribed by the original adventurers had fallen short of the amount required to finish the war, and being in want of further supplies, passed a law, that whosoever advanced one fourth more than his original share, should be entitled to as much land as if he had actually doubled his subscription; and that if any adventurer refused to make such advance on his original share, any other person, on paying it, should reap the benefit of the doubling clause, provided he repaid to the adventurer the sum at first subscribed. With great exertions, and by the determined interference of the Earl of Kildare, it was at length determined that the adventurers should receive lands for the money actually advanced by them, and no more. The Irish parliament, however, could only frame heads of a bill to this effect, which was liable to be modified by the king and privy council in England. Thither, therefore, all parties interested sent agents to defend their respective claims. London became the scene of controversy, intrigue, cabal, and even violence. The Irish called for the fulfilment of the articles of the peace of 1648. Ormond, who hated the Catholics even more than he did the regicides, persuaded the king that such fulfilment would be detrimental to his favourite scheme of maintaining an English interest in Ireland. Richard Talbot, afterwards Lord Tyrconnel, the advocate of the Irish, finding reason and justice ineffectual, challenged Ormond. The latter made his complaint to the council; Talbot was committed to the Tower, and detained there till he made an humble submission. The bill, with all its clauses, received the royal assent, and was sent back to Ireland, where it was adopted by both houses of parliament.

But the passing of the act was not sufficient to render it operative. Every one was dissatisfied with it. Even the adventurers, whose interests were best guarded by it, exclaimed against it most loudly. They considered the rejection of the doubling ordinance as the deprivation of so much of their justly purchased property. The land granted to the nominees, the number of whom had been increased by the king, was looked upon as so much cut off from the common fund whence they were to be repaid. The restoration of church property was peculiarly galling to their religious prejudices. The Protestant officers felt that their security was greatly diminished by large grants lavishly made to some of the king's special favourites. The Catholics complained that, so far from having justice done to their services, their agents were not even admitted to plead their cause before the council.

Ormond, now elevated to the rank of a duke, was sent over as lord-lieutenant to calm these effusions of anger, and to settle in the most amicable manner the conflicting interests of the parties. The first proceedings were those of the commissioners of innocency, who soon found that the number of those who could clearly establish their innocence, even before a court cautiously and carefully composed of Englishmen and Protestants, was inconveniently great, and excited the most serious alarm amongst the other party, who felt that every acquittal abstracted so much from the fund to which they themselves had to look for a settlement. Out of a hundred and eighty-seven cases adjudicated in the first three months, a hundred and sixty-eight were pronounced innocent, and but nineteen condemned. The House of Commons called upon the lord-lieutenant to make the qualifications more rigorous. The more violent of the old parliamentary soldiers laid a plan for a general insurrection. Ormond was steady. He put down the conspiracy, and executed a few of the ringleaders. He refused to make any change as to the qualifications. But he contrived to effect, by an evasion, what a regard for consistency of character had made him reject in public. Upwards of four thousand cases had been entered, and, from the number already decided, and the character of the decisions, it was felt that by much the greater proportion of the Catholic proprietors would be restored to their estates. To prevent such an occurrence, the time of the sitting of the court was limited to a fixed number of days, during which not more than one fourth of the claims could by any possibility be heard. It then closed, and thus upwards of three thousand ancient and respectable Irish families were stripped of their fortunes, without even the form of a trial before a court specially constituted to do them justice. The injured parties applied to the king; but he refused to listen to them, and they were irremediably ruined. Though their claim was rejected, however, its justice was recognised by a concession, and the lord-lieutenant was permitted to select twenty out of the three thousand, to be restored to their estates as objects of special favour.

To remedy, in some degree, the defects of the act of settlement, a bill was brought into parliament, chiefly by the instrumentality of the Duke of Ormond, which made a few alterations in some of its most obnoxious provisions. This is known by the name of the act of explanation. The two together form the tenure under which by much the greater part of the landed property of Ireland is held; they have therefore been quaintly, and with more regard to their binding force than their justice, styled the Magna Charta of the Protestants of Ireland. To account for the Duke of Ormond's conduct towards his former friends, to whom during the war he owed so much, and his master every thing, and his sacrifice of their interests to the bitter enemies both of himself and the king, it may be sufficient to mention, that his estates, which, before the breaking out of the civil war, had yielded but about L.7000 per annum, now brought him in a yearly income of upwards of L.80,000, in addition to the pecuniary grants made him for losses during the disturbances. The acts which ruined so many of the adherents to the royal cause secured him in the undisturbed enjoyment of this princely income.

Notwithstanding the apprehensions arising from the still uncertain state of title, the condition of the country began to improve with a rapidity alarming to the English, who were now suffering through a decline of their domestic trade, which prejudiced persons imputed in a great degree to the excessive importation of Irish cattle. To prevent the supposed ill effects of this, acts were passed prohibiting the Irish from sending cattle or provisions into England after the first of July, which exclusion was afterwards extended to all periods of the year. So strong was the prejudice, so powerful the alarm, that when the Irish parliament, through a wish to alleviate the sufferings of the people of London after the great fire in that city in 1666, sent them a free gift of thirty thousand oxen, the only wealth of the country at the time, the well-intended donation was rejected, as an attempt to evade the prohibition under the mask of benevolence. The king endeavoured to alleviate, though he was too weak and too timid to prevent, this impolitic act of injustice. He issued an act of state, permitting the Irish to export to foreign countries all commodities of their own growth and manufacture; and the Duke of Ormond, on his part, encouraged the woollen manufacture, for which the country was peculiarly fitted, from its capability of rearing sheep, and its water-power for machinery. He brought in foreigners acquainted with the processes of the manufacture, established a board of trade in Dublin, and encouraged factories on the Suir. His attention was also directed to the improvement of the linen manufacture. But his laudable efforts were thwarted by his enemies at court, who persuaded Charles to recall him. Lord Robarts, who was appointed in his place, rendered himself so offensive to all parties, that he was soon removed, and his place supplied by Lord Berkeley, who was also as speedily withdrawn, in consequence of his being active in procuring a commission of inquiry as to frauds practised on the Catholics in the adjudication under the act of settlement. The government of Lord Essex, his successor, was equally short-lived; and it was found necessary to restore Ormond, as the only person sufficiently acquainted with the state of parties in Ireland, to manage the country without danger of a sudden explosion.

Shortly after his return to office, the Popish plot occurred. The devisers of this execrable contrivance endeavoured to involve the Irish in a share of the guilt. Charges were made against Talbot the Catholic archbishop of Dublin, Lord Mountgarret, and Colonel Peppard, as being principals in it. On investigation, the first of these imputed conspirators was found to be labouring under a complication of disorders, beneath which he soon afterwards sunk; the second was bedridden through age; and the third was entirely unknown. The Duke of Ormond, more probably through a conviction of the necessity of yielding something to popular clamour, issued two violent proclamations. The one required the relations of tories to be answerable for them, and also that the priests of parishes in which a robbery or murder had been committed should be transported, unless the offender were delivered up to justice within a fortnight; the other prohibited Catholics from entering Dublin Castle, or any fortified place, and caused all fairs to be held without the walls of cities and corporate towns. But restraints, however rigorous, were not sufficient. The bigotry of the time called for a victim. Plunket, the Catholic archbishop of Armagh, was accused of being the instigator of a plot to raise seventy thousand men to overturn the government. He was sent to London, tried there for a crime committed in Ireland, denied either time or means to bring over witnesses, condemned as a traitor, and executed at Tyburn, professing his innocence to the last. The only subsequent act of Charles's reign, of consequence enough to merit notice, was a second attempt to deprive Ormond of his power. And it proved successful. Partly from a plea of his advanced age and increasing infirmities, partly from a necessity avowed by the king of removing from office several of his friends, the sword was taken from him and assigned to his relative Lord Rochester.

All the political arrangements consequent on the accession of James II. indicated a settled and systematic determination to disturb, if not wholly to nullify, the provisions of the act of settlement. Talbot, afterwards Earl of Tyrconnel, was placed over the army, which he immediately began to new-model, by cashiering and disbanding most of the Protestants, and bringing Catholics into their places; and by disarming the militia, which consisted chiefly of Protestants, under the plea that they were suspected to have been connected with Monmouth's rebellion. These apprehensions were still further increased by the promotion of Tyrconnel to the chief government. The first overt act was made against Dublin College, by nominating a Catholic to the professorship of the Irish language, which was defeated on the ground that no such professorship existed. An attempt made to appoint a Roman Catholic to a fellowship was frustrated by the gross incapacity of the person recommended.

The king's attempts against the Irish corporations were more successful. In order to carry into effect all his changes, the sanction of an Irish parliament was necessary; and to effect this, it was equally necessary to secure a majority in the boroughs, in which the Protestant interest had hitherto been almost exclusively predominant. Tyrconnel caused all the charters of these bodies to be seized into the king's hands, on the plea of violation or non-performance of conditions, and granted new charters, so arranged as to throw the whole of the borough influence into the hands of the Catholics. A few of the corporate bodies still hold under these charters; but the great majority of them having been passed after the abdication, are considered as of no authority in the courts of law.

On the landing of the Prince of Orange in Torbay, Tyrconnel received orders to send over four thousand men to England. So little prepared was he at the time to meet the exigency, that he found it necessary to withdraw the garrison from Londonderry in order to make up the number. But he soon became sensible of his error. The Protestants in the northern counties had already been roused to a movement of self-defence, in consequence of an anonymous letter sent to Lord Mount-Alexander, warning him of the intention of an immediate insurrection to extirpate them. Just at the time, a Roman Catholic regiment, lately raised by the Marquis of Antrim, had been ordered to Derry in room of the troops sent to England. The appearance of the men, now approaching the town, noway tended to diminish the feelings of alarm already excited by the previous warning. The first division of the newly-arrived regiment was within a few hundred paces of the town, when several young men, said to be apprentice boys, hurried armed to the gate, shut out the soldiers, hastened to the walls, pointed the guns, and threatened them with destruction if they attempted to force their entrance.

This decided act of the people of Derry was followed up by all the northern Protestants. The town of Enniskillen was secured in a similar manner, and armed associations were formed throughout every part of the province, to maintain the Protestant religion, and secure the dependency of Ireland. The first act of these bodies, after providing themselves with the means of resistance, was to apply to William. But he had already opened a treaty with Tyrconnel, to whom he sent General Hamilton, then prisoner with him, under a promise, that if he failed in gaining over Tyrconnel, he himself should return. Hamilton's conduct on the occasion was inexcusable. Instead of using arguments to persuade Tyrconnel to submit, he encouraged him to persevere in the cause of James, and remained with him instead of redeeming his parole, and proved his zeal in the cause he had thus faithlessly adopted, by heading a body of troops in Ulster, by which the whole province, with the exception of Derry and Enniskillen, was brought again under its allegiance to its former king.

James soon afterwards landed at Kinsale with a small body of French forces, having declined the aid of a more powerful armament, from a wish to be indebted for his restoration to the unassisted loyalty of his own subjects. On arriving at Dublin, he was welcomed with loyal addresses from all ranks and classes, amongst which the Protestant clergy were not less forward than others in their professions of zealous attachment. Finding himself at the head of what he considered as an unanimous people and a large army, his first movement was the reduction of the city of Derry, which, instead of listening to terms offered by Tyrconnel, resolved upon an obstinate resistance; expelled the governor set over the city by the king, upon a well-founded suspicion of intended treachery on his part; marshalled themselves in regiments; chose for leaders in this desperate attempt, George Walker, a clergyman of the established church, who had already signalized himself by raising a regiment of a thousand Protestants, and Major Baker; and, turning their guns against James, who, from a mistaken reliance on his personal influence, had approached the walls, compelled him to retire. The sword was now drawn between king and subject. The men of Derry had not only renounced their allegiance to their sovereign, but defied his power and insulted his person. James, convinced of the irresistible force of the numbers brought against the place, and of the futility of their means of resistance, their numbers not being more than seven thousand men, and these undisciplined and badly armed, the place unprovided with military stores, or even sufficient quantity of provisions, and the defences by no means adequate to resist the advances of a well-organized besieging force, returned to Dublin, leaving the conduct of the siege to Marshal Rosen, who had been a German officer in the French service. After some feeble attempts at gaining the town by storm, Rosen adopted the surer though more tedious method of blockade. The inhabitants were soon reduced to extreme privations, yet still they adhered to their determination of holding out. After upwards of two months suffering, they were cheered by the appearance of a fleet sent by William to their relief; but, after an empty display of assistance, Kirke, who commanded it, sailed away to Lough Swilly, where he employed his time in sending supplies to Enniskillen, which stood less in need of them. Still the garrison persevered in its defence. Rosen, enraged at their obstinacy, ordered all the Protestants in the neighbouring districts to be driven under the walls, in order to expedite the extremity of famine. The townsmen, in retaliation, prepared to hang up all the prisoners on the town walls. An express order from James forced the besieging general to relinquish this inhuman device for augmenting the horrors of war. The wretched sufferers were allowed to return home, and the town's people adroitly seized this opportunity of recruiting their strength, by taking in some of the younger and more vigorous, and sending away in their stead those exhausted by the hardships of the siege. After the garrison had been reduced to the necessity of subsisting on food loathsome to humanity, Kirke made a second attempt for its relief. A frigate and two provision ships sailed up the river, broke the boom thrown across it to obstruct their passage, and entered the town uninjured. The Irish army, whose hopes of success had rested wholly on the effects of famine, raised the siege in despair. The town's people, though reduced to half their original number by the casualties of war and sickness, had the hardihood to issue out in pursuit of the retiring army; but their temerity was punished by a severe check. About the same time the Enniskilleners gained a signal victory at Newtown-Butler, over a body of the enemy three times their number.

The military career of James in Ireland was neither creditable nor fortunate; his political efforts during the short period of his Irish government remain to be canvassed. A parliament was assembled in Dublin, in which the Protestant party, as might have been expected, was considerably outnumbered by the Catholics. One of its first acts was the attainder of about two thousand Protestant noblemen and gentlemen, adherents of William, whose estates were to be forfeited, unless they surrendered before a certain day, and who, if found guilty, were to be excluded from the benefit of a royal pardon; an act almost equalling in the extent of its powers, and the severity of its inflictions, the rigours of the act of settlement. The other measures of this parliament were of a different character; one was an act for establishing liberty of conscience, and repealing all such as were contrary thereto; another, connected with religious observances, directed that all should pay their tithes to the pastor of their own persuasion. A bill was also brought in to repeal the act of settlement, which was carried after much opposition from the Protestant bishops, and some of the lords. Another to prevent appeals to England was also carried, though with much difficulty. Two more, the one to repeal Poyning's law, the other to establish inns of court in Dublin, were opposed by James himself, who, still fondly clinging to the hope of a restoration to his seat of dominion in England, was averse to whatever had a tendency to diminish the dependency of Ireland. His conduct with respect to the circulating medium is the most unjust, as well as the most impolitic, of his measures. Parliament had voted him a subsidy of twenty thousand pounds a month. He doubled this sum by a royal ordinance. The money, notwithstanding votes of parliament and kingly proclamations, came in slowly. James erected a mint in Dublin, where he had large quantities of base metal coined into pieces of large nominal value. The plan, as a financial project, proved a complete failure, bringing discredit on the deviser, and inflicting injury on the friends of his cause, who were the ultimate sufferers by the depreciation.

Whilst James was neglecting his military operations in the north of Ireland, and injuring his credit and resources by his financial mismanagement in Dublin, his antagonist William, now freed by the death of Dundee from the apprehension of a Scotch invasion, was making extensive preparations for carrying on the war in Ireland. In the summer of 1689, his favourite general Schomberg landed near Carrickfergus, with a well-appointed army of ten thousand veterans. After taking that town, which surrendered on honourable terms, he moved southwards to Dundalk, where the scarcity of provisions, and the approach of the Irish army under James, obliged him to halt and encamp. His position was low and unhealthy, his camp ill supplied with provisions. His men sunk rapidly, through sickness and inaction. James, though much urged to it by his officers, could not be prevailed upon to hazard an assault. After remaining some time opposed to each other in a state of inaction, Schomberg took advantage of the arrival of some fresh troops to change his position, and retrace his steps towards Carrickfergus, where he was more secure against the necessity of combating to disadvantage with a superior force.

Next year William resolved to take the field in person. He landed early in June at Carrickfergus, and being joined by Schomberg with the remains of his shattered forces, advanced southwards in the same direction that had formed the line of march in the last campaign. His forces now amounted to six and thirty thousand men, the greater part veterans, who had proved themselves on the Continent. James's army had been in the mean time furnished with a supply of five thousand Frenchmen; but these were raw and undisciplined, and procured by an exchange of an equal number of Irish, the flower of his army. After retreating before his rival from Dundalk to Drogheda, he at length took up a position on the south side of the Boyne, where, contrary to the advice of all his officers, he determined to make a stand, and to set his chance of dominion on the hazard of a battle. William, whose disposition and circumstances equally urged him to bring the contest to an immediate decision without hesitation, prepared to force the passage of the river. Whilst engaged in reconnoitring the enemy's arrangements, he received a wound on the shoulder from a piece of artillery levelled at him from the opposite bank, but not sufficient to prevent him from appearing at the head of his troops in the ensuing day's engagement. The next morning his army, headed by himself, moved to the attack in three divisions. Crossing the river where the water in some places came up to their breasts, his troops gained the opposite bank, notwithstanding a galling fire from the infantry, by which they were lined, and repeated charges of the Irish cavalry led on by General Hamilton. Schomberg was killed, as is supposed by a chance shot from his own soldiers, in the confusion of one of these desperate assaults. Callimote, the leader of the French Protestants in William's army, also fell during the passage. Walker, likewise, the clerical defender of Derry, fell here. When his death was reported to William, the only remark made by the cold Dutchman was, "The fool; what business had he there?" The Irish, after some vain efforts to drive back the enemy into the river, in one of which Hamilton was taken prisoner, finally broke and quitted the field, thinking only of making good their retreat.

Whilst William was thus actively engaged in asserting his title to his newly-acquired throne, James was standing aloof on the hill of Donore, an idle spectator of a struggle which involved the fortunes of himself and all his adherents. On seeing the discomfiture of his army, he immediately fled to Dublin, and thence to Waterford, leaving directions to have the bridges broken down after him, to check his pursuers. William, adopting the same system towards him as when he had driven him from England, allowed him to continue his flight unmolested. Proceeding to Drogheda, he forced it to surrender on a threat of military execution in case of resistance, and thence continued his march without interruption to Dublin, holding out offers of protection to the peasantry, who accepted his protection, but declaring that he would leave the leaders, of what he chose to call a rebellion, to the chances of war. The main body of the Irish army retreated to Limerick and Athlone, placing the strong line of the Shannon between themselves and their victorious enemy. An attempt made upon Athlone by General Douglas was unsuccessful. After being baffled in an attempt to force a passage there, and in another at Lanesborough, lower down the river, he was forced to desist and retire to Dublin. A similar attempt made by William upon Limerick met with the same termination. Relying for success on the dissensions that existed between the French and Irish officers in James's army, he advanced to that town, carrying with him only a field train of artillery. On being apprized of his error by the formidable aspect of defence presented by the garrison, he sent for his battering train from Dublin, which, when within seven miles of his camp, was attacked and totally destroyed by a sortie of General Sarsfield. William, however, was not of a temper to be easily discouraged. With two pieces which had escaped the fate of the others he effected a breach, and proceeded to attempt an entrance by storm; but the breach was defended so gallantly that he was forced to retreat and raise the siege, after having suffered a loss of two thousand of his best men. The urgency of his affairs in England obliged him to go thither, leaving the command of the army to his generals, Solmes and Ginckel. The war was carried on during the winter, chiefly from a suggestion of the Earl, afterwards the celebrated Duke, of Marlborough, who proposed the taking of Cork and Kinsale, so as to secure the command of the southern coast. The suggestion was adopted, and its execution intrusted to the proposer of it. The fortifications of Cork were in a state of great dilapidation; the place was in a hollow, commanded by the surrounding mountains. After a short resistance, the only remarkable feature of which was the death of the Duke of Grafton, one of the natural sons of Charles II., the town surrendered on condition of protection to persons and property. But it was with much difficulty that the commanding officers enforced the observance of these terms. As soon as the troops had entered, a tumult was excited, the governor was wounded, the Earls of Tyrone and Clancarty narrowly escaped, and the houses of many Catholics were plundered. Kinsale, which was afterwards invested, presented more difficulty. The garrison abandoned the town, and confined their defences to two castles. One of these, the old castle, was soon stormed; but the other held out until its garrison procured permission to march out with their arms and join the main body of the Irish. Ginckel, after the capture of these places, attempted to carry the war into the west of Cork and Kerry; but his troops were foiled in the mountain passes, and forced to return with loss. Whilst the military operations were proceeding thus languidly, the civil officers of King William were more active and successful in securing their own interests, by the confiscation of the property of the adherents of King James. The forfeitures made by them comprehended a million of acres, the property of three thousand nine hundred and twenty-one sufferers, and were valued at three millions three hundred and twenty thousand pounds. The injustice of inflicting such a penalty on adherence to the cause of a rightful sovereign can only be surpassed by the means of its enforcement. The Irish gentry who possessed estates were indicted for high treason in their respective counties, and the causes then removed by *certiorari* into the King's Bench in Dublin. Thus, in most cases, the accused persons were deprived of the means of making their defence. In many, they were ignorant even of their accusation, until they found themselves stripped of their patrimony by the sentence of the court. At the same time rumours of plots and conspiracies were set afloat, and proclamations issued in consequence, assessing the Catholic inhabitants of peaceable counties for injuries to Protestant property in others, excluding from protection those who had sons in the enemy's quarters, prohibiting assemblages of more than ten Catholics, and subjecting to transportation the

History. parish priest of places where such assemblages were held. These proceedings drove the great body of the Catholics to desperation. They saw no hope but in the subversion of a government whose establishment was to be secured only by their utter ruin.

Military operations recommenced vigorously at the beginning of summer. St Ruth, who had been sent from France to take the chief command, determined to make a stand at Athlone, which he strengthened with some works. Ginekel directed his main force against it. His first assault failed. After a delay of nine days spent in preparations, a second attempt was made with still less effect. Not only were his troops repulsed, but his works were burned. St Ruth, intoxicated with his success, withdrew the greater part of his men from the defences, in spite of the warnings of his Irish officers. Ginekel, aware of the inconsiderate movement, took advantage of it, and forced the passage of the Shannon by surprise, whilst St Ruth was celebrating his victory by balls and entertainments in his camp at some distance. The Irish general then retired to Aghrim, on the borders of Galway, there determined to make a final stand, on a position chosen by himself. He was soon followed thither by the English, who attacked the position with undaunted intrepidity. For some time the contest was doubtful; but the death of St Ruth, who fell by a cannon-ball in the heat of the action, decided its fate. Whether from jealousy or contempt, this foreigner had avoided communicating his plans to the Irish generals who were to execute them. His sudden death, therefore, left the army without a head. All was confusion; and Ginekel, taking advantage of this state of things, pressed on and obtained an easy, but not a cheap victory. In the preceding struggle, upwards of two thousand of his men had fallen. The loss of the Irish, which occurred mostly in the rout, exceeded seven thousand.

The remains of the Irish army fell back upon Limerick. This city was now the only place of any importance that held out. Galway had surrendered upon favourable conditions. The garrison of Banagher, on declaring their determination to return home after surrendering, were supplied by their conqueror with the means of proceeding thither. Ginekel, who had remained some time inactive in Galway, hoping that terms of accommodation would be offered, as Tyrconnel was now dead of an illness said to be caused by disappointment, and the lords-justices who succeeded him were inclined to make terms, provided the interests of the general body of the Catholics were secured by them, at length opened the trenches before Limerick. At first the operations of the besiegers proceeded but slowly. Having, however, made themselves masters of a pass across the Shannon, through the treachery of Colonel Clifford, the officer who commanded there, they were enabled to invest the town on all sides. This advantage was followed by an assault on one of the gates, which was urged with so much ardour, that the officer there thought it necessary to raise the drawbridge with so much precipitation that upwards of a thousand of the garrison were left on the outside, exposed to the besiegers' fire. The greater part of these unfortunate victims were killed either by the enemy or in attempting to swim the river; a few were captured. The act itself was condemned as over hasty. The officer who gave the order for it was a Frenchman, and his conduct was imputed to bad motives. The bad feeling that had long subsisted between the strangers and the native troops was thus greatly exasperated. The latter, conceiving that their countrymen had been wantonly sacrificed, determined to seek for peace. Their resolution was encouraged by Ginekel, and a cessation of arms for the purpose of adjusting the terms of a treaty was the consequence. The news was immediately forwarded to the lords-justices in Dublin, just in time to prevent the publication of a proclamation, offering to the Irish in arms terms as liberal as they could have hoped for after a victory; granting, in fact, to the Catholics all the privileges they had heretofore enjoyed, and all they have since obtained. The lords-justices hastened to the camp, and in two days after their arrival the articles of Limerick received the signatures of both the contracting parties.

By this treaty it was stipulated that the Roman Catholics should enjoy the exercise of their religion, as during the reign of Charles II.; to which was added a promise that the king would endeavour to procure further security for them on this point, as soon as parliament should be assembled. It was further agreed, that all the inhabitants of Limerick, and those in arms for King James in the counties of Limerick, Clare, Kerry, Cork, and Mayo, should enjoy their estates, and be suffered to pursue their respective avocations unmolested; that the Catholic gentry should be allowed the use of arms, and should not be called upon to take any oath but that of allegiance; and, finally, that all the soldiers who were unwilling to submit to these conditions should be conveyed to the Continent at the expense of the English government. Two days after the signing of this treaty, a French fleet arrived on the coast with a large supply of reinforcements and military stores. But it was then too late. Nothing now remained in order to terminate the war, but the execution of that part of the treaty which permitted the Irish soldiery to choose between residence at home and service under a foreign but friendly power on the Continent. The Irish guards set the example; they all volunteered for the service of the king of France, seven individuals only excepted. Two regiments of Ulster Irish returned home in a body. Of the remainder of the Irish army, but one thousand horse and fifteen hundred foot remained. The generous self-devotion of those who sacrificed their country for their principles was but ill rewarded. On the arrival of the troops in France no quarters were assigned to them. The regiments were broken up, the officers reduced to lower grades, and the generals excluded from court. After some time, however, the value of their services was acknowledged, and the Irish brigade, during the succeeding continental wars, long maintained the highest character for fidelity to the cause it had embraced, and for the intrepidity it manifested under every circumstance of difficulty and danger.

A parliament was convened shortly after the ratification of the treaty. It was the first that had assembled after a lapse of twenty-six years of intestine commotion. Composed as it was of a great majority of Protestants, it testified little inclination to co-operate with the king's wishes, in adhering to the strict fulfilment of the articles of Limerick. The king evidently wished them to be maintained in the spirit as well as in the letter. The feelings of the leading party in parliament were sufficiently indicated in a sermon preached by the Bishop of Meath before the lords-justices, which inculcated the detestable doctrine that Protestants were not bound to keep peace with Papists. The first open breach that occurred between the government and the House of Commons was caused by the introduction of two money bills. According to the system of Ireland under Poyning's law, no bill could be brought into parliament until it had received the approbation of the king through the privy council. According to the principles of the British constitution, all money bills should originate with the House of Commons. The party opposed to the king took their stand upon the latter ground. One of the two bills was rejected altogether, and the other suffered to pass solely in consideration of the present exigency of affairs, and the pressing necessity of raising a supply for the king's service. Lord Sidney, in retaliation, suddenly prorogued the parliament, after reprehending the House of Commons sharply for what he styled an undutiful and ungrateful invasion of the royal prerogative. This act increased the general discontent, as several measures of importance then in progress were left unfinished.

A new parliament, assembled in 1695 by the Lord-deputy Capel, opened with an assurance from the throne, that the king was intent upon the firm settlement of Ireland upon a Protestant interest. Such a declaration was hailed with joy by the prevailing party. In order to support the king in this measure, a committee was appointed to consider what penal laws were in force. The following were found to be the principal: 1. An act subjecting all who maintained the supremacy of the church of Rome to the penalties of a *præmunire*, and requiring the oath of supremacy as a qualification for every office. 2. An act imposing fines on absence from the parish churches on Sunday. 3. An act authorizing the chancellor to appoint a guardian to the child of a Catholic. 4. An act to prevent Catholics from being private tutors, without license from the bishop. Having ascertained the actual state of restrictions on the Catholics, as they had existed previously to the treaty of Limerick, the parliament proceeded, not to secure them in the privileges guaranteed to them by that instrument, but to increase the number of penalties and restrictions, contrary to its spirit and tenor. The following statutes, passed by this parliament, formed the commencement of the system of restrictive legislation now known by the name of the penal code, which, when wound up to its acmé of intolerant severity, by the successive enactment of laws, each surpassing its predecessor in severity, was described by Burke as the acmé of refinement in political persecution. These acts were, 1. to deprive Catholics of the means of educating their children, either at home or abroad, except under Protestant teachers, and to prevent them from being guardians even to their own children; 2. to disarm the Catholics; 3. to banish Catholic priests and prelates. Having passed these acts in direct violation of the treaty, they proceeded to confirm those articles, or so much of them as might consist with the safety and welfare of the king's subjects in these kingdoms. The bill took care that the precautionary proviso should not be a dead letter. It abrogated the articles which provided for the security of the Catholics from disturbance on account of their religion, which confirmed them in the possession of their estates and the exercise of their profession, which allowed them the use of arms, and which required the oath of allegiance only as a test of their loyalty. The bill passed the House of Commons with little difficulty. But in the House of Lords, where several of the Catholic peers still had seats, it was strenuously resisted; and when carried, a protest against it was entered on the journals by thirteen peers, six of whom were bishops. This mutilated ratification of the treaty was followed up by three other penal laws: 1. To prevent the intermarriages of Protestants and Catholics; 2. to prevent Papists from being solicitors; and, 3. to prevent them from being gamekeepers.

The spirit of religious intolerance that gave birth to these acts was not the only evil that checked the prosperity of the country. The commercial spirit of monopoly of the English manufacturers, who had long viewed with a jealous eye the increase of the woollen manufacture in Ireland, to which the cheapness of living and the excellency of the pasturages afforded peculiar advantages, prevailed on the king to make a solemn assurance that he would do all that in him lay to discourage that manufacture, adding as a mitigation of a declaration so iniquitous, that every encouragement should be afforded to the linen manufacture. The former part of the promise was rigidly adhered to, the latter was disregarded. Every attempt to establish the linen manufacture in the south of Ireland failed, chiefly from the opposition given by the clergy to the introduction of an equitable modus for the tithe of flax.

Whilst parliament was thus employed during the reign of William, in undoing the bonds of the treaty of Limerick, the court of claims appointed to investigate and dispose of the lands forfeited by the adherents of James was equally active in its invasion of their property. Amongst the chief sufferers by the decisions of this court was the Earl of Clancarty. It appeared doubtful whether his noble estate should be included amongst the forfeitures. The point was decided by a declaration of the grand jury of the county of Cork, which resolved that its restoration would be prejudicial to the Protestant interest. It was therefore sold, under a decree of the court. A subsequent attempt made in his favour in the reign of George II. was not only equally unsuccessful, but all attempts at a repetition of it were crushed by a vote of the House of Commons, that any lawyer who pleaded in his behalf should be deemed an enemy to his country.

The annals of Ireland during the reign of Queen Anne are merely a record of the exertions of the Irish parliament to rivet and extend the penal laws. By an act passed in 1703, the father of a Papist who conformed to the established religion was incapacitated from disposing of his property by sale, mortgage, or bequest; and a Papist was prohibited from being guardian to his own child, who, on conforming, was to be taken from his parent, and given in charge to a Protestant. Papists were rendered incapable of holding lands for more than thirty-one years; and if the profit rent of such land was found to exceed one third of the actual rent, the benefit of the lease was to be transferred to the Protestant who made the discovery. They were also prevented from inheriting the lands of their Protestant relatives, and their own lands were to be gavelled after death amongst their children. The most extraordinary provision of this monstrous act, was the requiring the oath of abjuration, and the sacramental test, to be taken as a qualification for office and for voting at elections. The cause of its insertion is singular. The English government was at this time negotiating with the emperor of Germany for the toleration of Protestantism throughout his dominions. To press the enactment of severe laws against the Catholics at home at such a period, exhibited an inconsistency as absurd as it was iniquitous. An effort was therefore made to dissuade the Irish parliament from proceeding with the bill, but to no purpose. Knowing, therefore, that the majority of the lower house consisted of Protestant dissenters, the clause requiring the taking of the sacramental test was inserted by the English council, in the hope that the rigid puritans would reject the whole bill rather than saddle themselves with the disqualification. But they were mistaken. Bigotry prevailed over self-interest; and the puritans of the day acquiesced in the passing of a law, which deprived the conscientious members of their own persuasion of the right of exercising the most valuable privileges of freemen, rather than suffer their Catholic countrymen to participate in them.

This act was followed up by resolutions calling upon all the civil officers of the government to enforce its provisions, and declaring that the prosecuting and informing against Papists was an honourable service to the government. But this law, and these resolutions, were not deemed sufficient. In 1709 another act was passed, imposing additional restrictions upon the Catholics, by which they were prohibited from holding annuities for life; requiring the father of a conforming child to give in to the chancellor a strict account of the value of his property, in order to apportion a due share thereof to his support. Jointures were secured to conforming wives. Papists were forbidden to be assistants in schools. Popish priests who conformed were allowed a stipend of L.30 a year, that of a Protestant curate being L.50; and rewards were offered for the discovery of popish prelates, priests, and teachers, at the rate of L.50 each for the first of these classes, L.20 for the second, and L.10 for the third. A subsequent statute excluded Catholics from acting as sheriffs, and from sitting on grand juries, and even proceeded as far as to enact, that in trials arising out of statutes for strengthening the Protestant interest, the plaintiff might set aside a juror on the ground of his being a Papist. The example of the parliament was followed by the corporations. Bye-laws were enacted, excluding Catholics from every profitable branch of trade. The result was, that all the Catholic gentry possessed of the means of emigration quitted the country, as did all the merchants of respectability, carrying with them, to fructify in other and in hostile countries, the property which might have enriched that of their persecutors.

The system was now nearly complete. The Catholics were excluded from every opening to political power. They were not exterminated, because the land would have been valueless to the new proprietors, without the assistance of labourers sufficient to extract its produce. The effects of the system soon began to appear. The son of James II. made an attempt to recover his father's dominions in the beginning of the reign of George I. The new proprietary took the alarm. On the first rumour of his intended project against Scotland, a number of Irish Catholic gentlemen were thrown into close confinement. The government, however, ashamed of this unnecessary ebullition of terror, soon afterwards caused them to be liberated, even without payment of the customary fees. The alarm was futile. The Irish had not the means, nor even the inclination, to renew the contest. Their spirit was broken by the grinding degradation of the restrictions thrown around them. Yet, to make assurance still surer, these restrictions were increased by the addition of new clauses to the penal code, mostly of minor importance, by one of which Papists were excluded from voting in vestries for the assessment of money for repairing or rebuilding parish churches.

The Irish Protestants were equally active in asserting their own liberties, as in extinguishing those of the Catholics. An attempt made by the English House of Lords to exercise the right of ultimate jurisdiction in cases of disputed property, to the prejudice of the peers of Ireland, was stubbornly resisted; and though the dispute was cut short for the time by an English act, declaring that the British parliament had full power and authority to make laws to bind the people of Ireland, the acquiescence of the latter proceeded, as future events fully proved it, from a consciousness, not of the defect of right, but of power to assert it. In its resistance to another act of British interference the country was more successful. The coinage, particularly of copper, was deplorably defective both in quantity and in value. An application for a domestic mint, a right often before allowed and exercised, was rejected, and in lieu of it a patent was granted to an English brassfounder of the name of Wood to coin copper to a large amount. The pride of the Irish took fire, and the circumstances of the case elevated the feeling into patriotism. Amongst the opponents of Wood's patent, Jonathan Swift, the celebrated dean of St Patrick's, was most eminent. In a series of letters, published under the name of the "Drapier," he denounced the scheme as illegal and ruinous. One of the letters was deemed libellous, and a large reward was offered for the discovery of the author. But the fidelity of the dean's partisans bore him harmless; the storm passed over without injury to him. The invidious patent was recalled; and his grateful country has embalmed his memory in the immortality of patriotism.

The state of the Catholics was now brought down nearly to the lowest point of depression. An address of congratulation to George II. on his accession, presented to the lord-lieutenant by Lord Delvin, on their part, was suffered to remain unnoticed, except so far as to render so faint an effort an apology for still further restraints. A bill was brought in for excluding Papists from voting at elections. By another, lawyers and attorneys married to Papists were prevented from practising. Even converts could not hold the office of justice of the peace if their wives and children continued to be recusant; and persons plundered by privateers in the service of a popish nation were to be reimbursed by a levy on the goods of Roman Catholics only. A vote of the Commons, declaring any person who took legal steps for the recovery of his tithes of dry cattle, commonly called the tithe of agistment, to be an enemy to the country, threw the greater part of the burden of maintaining the Protestant clergy from the rich proprietor, whose land was wholly under pasturage, upon the Roman Catholic cotter, who was obliged to raise some grain on his little patch of ground for the subsistence of his family.

Whilst the Irish parliament were thus vigilant in cutting off from the Catholics all means of regaining political power, they were no less so in preventing any encroachment of the English government upon the rights they themselves possessed. The relations of these two latter parties towards each other after the Revolution were peculiar. The members of the House of Commons held their seats, not, as in Great Britain, by septennial election, but during the pleasure of the crown. Their tenure was therefore generally regarded as tantamount to a life estate, subject only to a dissolution on the demise of the crown. Hence they were virtually unrestrained by popular control. On the other hand, as the lord-lieutenant came over to Ireland but once in two years, to hold a parliament for granting the supplies, the management of the country rested with the lords-justices nominated to hold the reins of government in his absence, who were selected from among the most powerful of the great Protestant families. Their influence, in questions between the two countries, was therefore often directed to thwart the measures of the English cabinet, particularly when these seemed to interfere with their own aggrandizement. The operation of the penal laws, whilst it enslaved the Catholics, pauperized the country. The great mass of the population was deprived by them of the main stimulus to industry, the hope of improving their condition by their own exertions. The great proprietors found their land becoming of less value, from the neglect of agricultural improvement. The supplies for the service of government were therefore granted with a niggardly and reluctant spirit. The English cabinet hoped to cut the knot that thus linked them to the Irish parliament. An attempt was made to obtain a vote for the supplies for twenty-one years. The Irish aristocracy immediately took the alarm. However acquiescent in the general tenor of their votes, they now rallied, and the insidious attempt was rendered abortive by a majority of one.

The depression of the country, arising from the treatment of the Catholic part of the population, was endeavoured to be remedied by the extension of education, the formation of patriotic societies, and the execution of public works. To educate the Catholics, it was necessary they should first be converted, because by the penal code domestic education according to the principles of their own faith was prohibited. Schools were therefore opened, in which the pupils were taught the elements of literature and the useful arts, and were also clothed and fed at the public expense. Being established by letters patent from the crown, these obtained the name of charter schools.

Their professed object was the diffusion of useful knowledge; but as their primary process was based upon Protestant instruction, and as this, to be effective, required a total severance of the parental tie which linked the Catholic peasant to his family, the effort failed. The second element of national regeneration was attempted by the formation of a society, in imitation of the Royal Society of London, under the name of the Physico-Historical Society, for the improvement of agriculture, husbandry, and the useful arts, which afterwards merged into the Royal Dublin Society. The last-named element of improvement, the execution of public works, gave rise to the measure of inland navigation. But none of these were effective to the extent proposed by those who set them on foot. The great object was not merely to give Protestantism the ascendency, but to eradicate Catholicism; to realize, in fact, what was imagined by a fiction of law, when, in a case where a Catholic came into a court of justice, he was gravely told that the law did not recognise the existence of a Papist. Education, whether of the primary rudiments or of the higher departments of science, gave knowledge, and knowledge revealed the extent and gloom of degradation. Useful works required workmen, and thus circulated capital amongst the Catholic population, to which the undertakers were compelled to have recourse for the mechanical parts of such undertakings. A state of society so anomalous, in which universal liberty was the avowed principle, yet slavery, unmitigated by the protection which sordid interest extends to the preservation of individual property, was the practice, could not but be most precarious. The ruling party, aware of the danger of explosion, at length found itself compelled to give vent to the under-workings of the re-action against oppression, by a partial change of system. That of ever-increasing compression, painful and hazardous at all times, was found, in periods of general agitation or impending warfare, impracticable. The threatened invasion of England by the young Pretender was the crisis which led to a change of domestic policy towards the Catholics. Ireland, as the weakest point of the empire, was looked upon as the most exposed. The Irish population was numerous and discontented. Their deficiency in the means and the organization of war could be instantaneously supplied by the wealth of France, and by the long-proved skill and valour of their countrymen, the Irish brigades in the French service. To ward off the apprehended danger, Lord Chesterfield was sent over in the spirit of conciliation. To the Catholics, worn down by the action of half a century of increasing oppression, the slightest relaxation of the highly strained engine of oppression became comparatively a blessing. An accidental circumstance afforded the new governor an opportunity to evince the sincerity of his professions. Hitherto the Catholics had held their assemblages for religious worship in the most secluded and secret places. The rewards offered by the laws for the detection of their priests, or of those who attended their ceremonies, compelled them to the strictest secrecy. The floor of a building in one of the confined streets of Dublin, where mass was celebrated, gave way, and caused the death or mutilation of a number of the wretched beings, congregated to worship their God at all hazards, in the way in which they had been trained. Lord Chesterfield, with the tact which has immortalized him as a first-rate character in the annals of fashionable life, seized the opportunity of declaring openly that he would not be a party to a system of religious prevention, liable to the hazard of such results; and the meetings of Catholics for the purpose of religious worship were consequently winked at. Still, however, the spirit of the penal code remained unrestricted; and operative laws were passed during the government of this, the first of the tolerating lord-lieutenants, not only annulling all marriages between Protestants and Catholics, if celebrated by a Catholic priest, but also rendering the clergyman who performed the ceremony liable to capital punishment. The threatened storm from abroad blew over. The invasion of the young Pretender forms no part of Irish history. The Irish Catholic remained unmoved in his habits of passive obedience. The Irish Protestant returned to his parliamentary controversies with the ruling powers in England. Where there existed such a consciousness of overwhelming superiority on the one side, acting upon a spirit of domineering independence, checked by an internal conviction of weakness, the weakness of division, on the other, collisions between the English cabinet and the Irish ascendency party could not fail to be frequent and acrimonious; much less could such collisions fail to throw to the surface some of those restless spirits which political convulsions have shaken from their orbits of ordinary movement. A contest between the Irish privy council, which then exercised the most important parts of the legislative functions of government, and the corporation, stimulated Charles Lucas, a Dublin apothecary, to assert the rights of the latter. Though unsuccessful, he was not unrewarded. The death of the two representatives for Dublin gave rise to a contested election, an event of rare occurrence under the then existing constitution of the Irish parliament. Lucas was elected, under the pledge of vindicating, in the House of Commons, the perfect independence of the Irish legislature. This doctrine, first broached by Molyneaux shortly after the Revolution, in a treatise called the "Case of Ireland," was viewed with alarm by the English party in the house, and with jealousy by that of the Irish aristocracy. By the one it was viewed as a severance of the connection of sovereignty and dependence between the two countries, by the other it was felt to sap the foundations of their own domestic omnipotence. Passages of libellous tendency were extracted from Lucas's publications. The House of Commons declared him an enemy to the country, and passed a vote for his prosecution. He evaded the coming storm only by retiring to the Continent. On a subsequent vacancy, however, he was re-elected, and took his seat as one of the representatives of the people, which he retained till his death. The Irish parliament, arrogant where it felt secure in its own power, was tamely submissive under circumstances wherein an assertion of its just rights would have been truly creditable. A surplus revenue remained in the Irish exchequer. The English council insisted on the king's right to dispose of it at pleasure. The Irish Commons equally insisted on their absolute control over the public purse, without any interference from other quarters. The bill acknowledging the necessity of the royal consent to the appropriation of the surplus income was rejected by the Commons. The English council cut the matter short. The money in dispute was drawn out of the treasury by a king's letter, and the Commons passively acquiesced in the spoliation and insult.

In this state of torpid tranquillity, ruffled only by apprehensions of internal commotion, or by the agitation of partisan quarrels between the rival factions of court and country which divided the dominant party, Ireland continued to advance for nearly seventy years after the Revolution, until at length the elements of activity were roused by the reality of an actual invasion. In the year 1759, a fleet was fitted out in the French ports, for the avowed purpose of landing a large armament in Ireland. A small squadron under M. Thurot, supposed to be an advanced section of the main fleet, and intended to cause a diversion of the defending forces, landed in the north of Ireland, and took possession of the town and castle of Carrickfergus, with little opposition. After holding it a few days, the French commander, checked by the appearance of the general and determined resistance which was gathering around him through all the northern counties, deemed it expedient, instead of proceeding to the assault of the wealthy and undefended town of Belfast, which lay at but a few miles' distance, to re-embark. Any further repetition of his predatory incursions was prevented by the destruction of his little armament in the channel, in an engagement, in which Thurot himself lost his life.

The alarm excited by the threatened invasion afforded an opportunity to the Catholics to call the attention of the government to their sufferings. An address, framed by a committee of their body, was presented to the lord-lieutenant, making a tender of their allegiance at this critical period. Its favourable reception brought forward others of the same kind from every part of the country, and thus was the first impulse given to the movement for the repeal of the penal code. Another opportunity of echoing the sentiments contained in these addresses presented itself on the accession of the new king, George III. It was eagerly seized on, and the address was received with equal favour as the former. The state of the country required some vital change in its internal administration. The revenue was declining, and the peasantry were every year becoming more destitute and discontented. The wretched sufferers, attributing their misery to the exaction of tithes and the enclosure of lands hitherto left open in commonage, banded themselves together in large bodies at night, and destroyed the new enclosures; whence they at first received the name of Levellers, but were afterwards better known by that of Whiteboys, from their wearing white shirts over their clothes, to be known to one another in their nocturnal expeditions. From the invasion of property they proceeded to the attack of persons obnoxious to them, particularly tithe proctors, treating with wanton and barbarous cruelty those who fell into their hands. The government, instead of probing the evil to the bottom in order to effect a cure by the removal of the cause of irritation, retaliated by a series of severe and arbitrary laws, known by the name of the Whiteboy Acts, many of which are still in force. Attempts were made to connect those insurrections of desperate misery with the political movements of France. Rumours were circulated that the Whiteboys were encouraged by money from that court, and that their combination was the explosion of a plan for restoring the Pretender. A parish priest of the name of Sheehy, who had made himself obnoxious to the gentry in his neighbourhood by his exertions to shield the peasantry from their oppressions, was arrested on a charge of treason; and, though acquitted of that crime after a patient and long investigation by a jury in Dublin, he was, on his return home, again arraigned on a charge of murder, universally known to be false, and executed. The situation of the British government in Ireland at this time was extremely irksome and invidious. In order to carry on the public business smoothly, it became necessary to conciliate the great landed proprietors, who, through their borough influence, had the control of the House of Commons. They were to be gained over partly by allowing them a large share in the disposal of all places of trust and profit, and partly by indulging their enmity to the Catholics, who were still suspected of being cemented in a secret union for the recovery of their forfeited estates. The party which thus virtually ruled the country by playing the British government and the Irish people against one another, was known by the name of the Undertakers. They had a double object; the one to make the crown, as far as Ireland was concerned, dependent on themselves; and the other to check the spirit of liberty in the people, and at the same time to throw on the government the odium of the measures of which they themselves were the instigators. To break down this petty aristocracy, which had intruded itself between the prerogative of the crown and the rights of the people, the British cabinet resolved, in the early part of George III.'s reign, that the lord-lieutenant, who had hitherto visited the country only once in two years for the purpose of holding a parliament and passing the supplies, leaving the management of the country during the intervening period to two or three lords-justices chosen from among the leaders of the Undertakers, should reside permanently in Dublin, so as thus to be the immediate and ostensible organ of government patronage and influence. At the same time, to put a stop to the outcry against the mismanagement of the public income, which was attributed to the people's want of a sufficient check over their representatives, the duration of parliaments, which hitherto had terminated only on the demise of the crown, was limited to eight years, so that, as the parliaments then sat only ever second year, there should be four sessions between each dissolution. Lord Townshend, a nobleman of moderate political, but of great convivial endowments, was selected as the most fitting person to effect the change. He succeeded with much difficulty, some loss of character, and great expenditure of the public money. But the people felt no benefit from the change. The places and pensions, hitherto bestowed on the dependents of the Undertakers, were now lavished with augmented profusion on the creatures of the lord-lieutenant. The disappointed borough holders of the old parliaments felt their power in the House of Commons increased by the curtailing of the period of legislation. They threw themselves into the ranks of opposition, to thwart the measures of the government which they could no longer direct. The parliament was the arena for the struggle between the two parties, and the real interests of the country were disregarded. The severity of the Whiteboy Acts caused a temporary cessation of insubordination in one part of the country, only to give vent to it in another. The disturbances in the south had been imputed to Catholic conspiracy, aided by foreign influence. A similar systematized spirit of outrage now displayed itself in Ulster, which was chiefly inhabited by a Protestant population, that had already testified its loyalty during Thurot's invasion. The real cause of disaffection was the same in both parts of the country. High rents, and the rapacity of the agents of absentees, drove the people into insurrection. The assembled multitudes here took the name of Hearts of Steel. For their suppression, the legislature passed an act that offenders should be tried in counties different from that in which the crime was committed. The extreme severity and injustice of the law counteracted its operation. Dublin juries, disgusted at a measure so arbitrary and unconstitutional, acquitted the prisoners, and the law was soon repealed. Emigration to the American colonies was the consequence of the depressed state of the peasantry, and of the severity with which they were treated. The war with those colonies, by closing this vent for the discharge of the popular discontents, caused them to accumulate at home. It also increased their amount by the addition of other grievances arising out of the change from peace to war. America had been the great mart for Irish linens, now the only thriving branch of the national manufactures; it was also the great market for Irish provisions. The war closed the trade, and an embargo laid on provisions in favour of some great English contractors put a stop to their export. The country was also deprived of its portion of the regular troops, which the increasing emergency of the struggle with the revolted provinces called away. The sufferings of the people were intense; and the alarm of danger was shortly afterwards increased by the well-founded apprehension of an invasion from France, now the avowed ally of the Americans. To allay the spirit of discontent which was rapidly pervading all ranks, two measures were proposed, the one in England, the removal of the restrictions imposed there, as unwisely as selfishly, on Irish commerce; the other the relaxation of the penal code in Ireland. The commercial jealousy of the mercantile interest in England prevented the former; the latter succeeded so far as to allow Catholics to hold lands by lease for a long term of years. This boon, though it might excite the hope of more extended liberality, could avail little toward relieving the pressure of immediate distress. Want at home, and danger from abroad, stared the country every year more fully in the face. The landed and commercial interests called on the government for protection. The Earl of Buckinghamshire, then lord-lieutenant, a man of moderate abilities, returned for answer that the government had none to give. The people, urged on by the exigency of the crisis, resolved to arm themselves. Volunteer associations were not hitherto wholly unknown in the country. The military spirit of the nation had shown itself on many preceding occasions, in the readiness with which numerous bodies of men, assuming a self-formed and self-taught military organization, united together on occasions of local or temporary danger. The invasion of Thurot gave rise to some in the north, the outrages of the Whiteboys led to others in the southern counties. But such instances were temporary and local. The impulse now given to the public spirit, by the desponding reply of the government to the appeal for protection, was universal and permanent. The organization commenced in Belfast, to which the lord-lieutenant's answer had been more specially directed. The constituted authorities had told them they were not to look to them for protection, but to themselves. They took the hint, and formed several companies of self-armed, self-disciplined, and self-officered soldiers. The surrounding towns followed the example; and the government, acting in the spirit of its own suggestion, supplied these new-raised levies with arms. The flame of military ardour spread with unexpected rapidity through all parts, and the number of well-disciplined corps soon became so great and so formidable as to dispel all thought of invasion on the one side, and all apprehension of it on the other. The same spirit caused a re-action against the monopolizing restrictions of the British legislature. The people of Ireland entered into a very general combination to confine themselves to the use of their own manufactures. The sudden check to industry thus produced in England caused the supporters of the measure to reflect on its inexpediency; and the military display could not fail to attract their respect.

The people of Ireland now began to expect from their volunteer associations what, according to the principles of the constitution, should only be looked for from the legislature. These bodies were not backward in meeting such expectations. Assemblages of volunteer corps in Dublin and elsewhere passed resolutions that the king, lords, and commons of Ireland alone were competent to make laws to bind the people of Ireland. The political feeling thus excited increased the number of military associations; and, whilst in the parliament the old system of corrupt influence carried all before it by numerical majorities, the volunteers of Ulster, in the consciousness of their strength, held a meeting at Dungannon, declarative of the necessity of a thorough reform of the state of the representation, and of a combined exertion of the whole volunteer force of Ireland to procure it. The effervescence of patriotism was increased by the unsettled state of the administration in England; Lord North had resigned, and the death of Lord Rockingham put a premature end to his short-lived administration. The result as to Ireland was the dissolution of the parliament, against which the feelings of the nation were so highly excited. A new parliament was about to meet; and at the same time a meeting of delegates from all the volunteer corps in Ireland was to assemble in Dublin, to urge on the favourite measure of parliamentary reform.

At this time several individuals had raised themselves to the highest pinnacle in the scale of patriotism. The most remarkable was the Earl of Charlemont, who, after spending his youth amidst the elegancies of Italian refinement, devoted his maturer years to the service of his country at home. Next to him were Grattan and Flood, both members of parliament, both eager to establish the independence of their common country on sure grounds, yet fatally adverse to each other as to the foundation on which it was to be laid; the former considering a simple repeal of all English laws interfering with Irish rights as a sufficient disavowal of the assertion of supremacy, the latter requiring an open and explicit disclamation on the point. Grattan was successful, and the country voted him L.50,000. The breach between the rival patriots was irremediable. Grattan remained at home to continue the struggle for securing the newly-gained rights of his country. Flood soon afterwards retired to England, where a seat in the British legislature flattered him with a more enlarged sphere for the display of his powers. But he failed, and was no longer named as a patriot or statesman.

The meeting of the new parliament and of the volunteer convention took place simultaneously. The first and only act of any consequence adopted by the latter, was a resolution as to the necessity of a reform in parliament; which having been immediately afterwards introduced by Mr Flood into the House of Commons, was there rejected by a large majority; and the convention, partly through an apprehension among many of its members, of dangers from a collision between two representative bodies, both emanating from the same source, and both claiming to be the constitutional organ of their constituents, and partly through a manœuvre of some of its leaders, quietly adjourned, and never afterwards assembled.

Assemblages of large bodies of armed men, unconnected with and beyond the control of the government, could not fail to alarm the ruling powers. The union of these bodies into a deliberative meeting, for the avowed purpose of influencing the legislature, was still more alarming. The first effort of the volunteers to attain this position had been baffled. The meeting of delegates was dissolved; but it might, and there was every reason to suppose that it would, be re-assembled. To prevent such a recurrence by violent means was dangerous. The volunteer body was numerous. It counted upwards of 100,000 men, embracing the greater part of the wealth and respectability of the country, in its ranks; its numbers and discipline were yearly increasing. The consequences of a hostile collision with such a body, particularly at the close of an unsuccessful war, commenced with the avowed determination of crushing the spirit of independence in the American colonies, were fraught with great hazard. An attempt was therefore made to break up the strength of this body by internal divisions. The Catholic question effected this. The volunteers were almost exclusively Protestants. The extension of rights to a portion of the population, so long held in a state of passive degradation, was viewed by many of them with a jealous eye. They looked upon every new concession to the Catholics as so much abstracted from themselves. Still, however, the Catholic cause was gaining ground.

The extension of a free trade to Ireland had afforded the means of accumulating property. It was eagerly seized on by the Catholic merchants and traders. The lately conceded permission to hold land on long leases gave the holder of such property a fixed position and weight in the country. New laws, framed in the spirit of the increasing liberality of the age, extended their rights. They were permitted to purchase, hold, and dispose of land, by will or otherwise, as freely as Protestants. The penal acts prohibiting the celebrating or hearing of mass, keeping horses above the value of five pounds each, instructing their own children, or acting as teachers, were repealed; as were those taxing them for the losses sustained from privateers, obliging them to pay Protestant watchmen, excluding them from residence in particular towns, and some other petty and irritating restrictions. Still they were far from being on a political equality with their Protestant countrymen; and at the very time that the severity of the code was thus relaxed as to property, new laws were passed still further contracting their political rights. By one of these they were debarred from admission into the Inns of Court; by another the English act of William III. excluding them from sitting in parliament, was formally enacted in Ireland. The passing of it attracted but little notice, as the act of William had been hitherto passively acquiesced in by the Catholic body.

Whilst the government was successfully busied in sowing the seeds of disunion amongst the volunteers, it paid little attention to conciliate the people by economy or good management. The reckless system of lavish and profligate expenditure introdueed by Lord Townshend, to break down the monopoly of the Undertakers, was persevered in to secure majorities in the House of Commons. A feeble effort made by the Duke of Buckingham to retrench and restore order into the finances only led to his recall. Yet it was soon found that a government resting on majorities thus purchased depended on a very frail security. The mental derangement of the king in 1789 showed the futility of such reliance. The English cabinet wished to restrict the Prince of Wales in the discharge of the regal powers intrusted to him as regent. The Irish privy council was prepared to follow the example. But the opposition in parliament, anxious to extend their own influence by gaining over the heir-apparent, who had till then always made professions of great liberality of political opinion, resolved to grant him the regency of Ireland, with no restrictions beyond those imposed by the constitution on the sovereign himself. An address to this effect, voted by both houses of parliament, in opposition to the lord-lieutenant, was forwarded to London. The sudden and unexpected recovery of the king prevented its effect. But the British minister, having now so fully before him a warning of the consequences that might result from similar collisions of the two legislatures upon future questions, seemed fully determined to seize on every opportunity of preventing it, by taking measures for effecting a union of the parliaments of both countries, similar to that which took place in Scotland at the commencement of the century. The prevalence of opposition to the wishes of the English cabinet was as transient as it had been sudden. The members who voted against the ministry on the regency question were again found in their places on all ministerial questions, with the exception of those whose rebellion had been too gross and daring to admit of pardon; and the parliamentary management of the country began to subside again into its former state of torpidity.

But the calm was not to be of long duration. A new element of convulsion was at work. The French revolution broke out in the same year in which the king's insanity had caused such excitation. For some time it produced but little effect on the popular movements in Ireland. The Protestants, indeed, began to call more loudly for reform, and the Catholics to press more openly for admittance into the pale of the constitution. Both were disregarded. The government felt itself strong in its majorities, and in the plenitude of its means for securing them. The question of reform was disregarded; that of Catholic relief was not only scouted with marked contumely, but, during the ensuing recess in 1792, every exertion was made on the part of government to draw forth from the grand juries of the several counties the strongest resolutions against any further concessions. Yet the very next year a bill was introduced into parliament by the government, for extending the elective franchise to the Catholics, which was passed by a majority nearly equal to that which had refused to take their claims into consideration in the last session. Bills for amending the representation, and for disqualifying placemen from sitting in the House of Commons, were also introduced. The promises of reform thus held out induced the minority to acquiesce in several coercive measures, particularly one against the holding of conventions by delegation. Enactments of the latter character having been secured, that of reform was allowed to languish, and, next year, was rejected by an overwhelming ministerial majority. The French war in which England was now involved had been the cause of this sudden burst of concession; but when the means of carrying it on, and of checking by severity any efforts to excite discontent at home, had been assured, the mask was thrown off, and the management of affairs carried on with increased profligacy of expenditure, and disregard of public opinion. The advocates of reform, despairing of any change of measures from parliament, endeavoured to carry the question of reform by a pressure from without, through the agency of voluntary associations. They formed a Whig Club, which afterwards was superseded by that of the United Irishmen. One of the leading features of both societies, especially of the latter, was the advocacy of the Catholic question, as it now appeared evident that the question of reform was hopeless, without the previous admission of the Catholic body to their rights of freemen. The government, after some further perseverance in measures of harshness and restraint, heightened by the increased violence of the leaders of the people, the principal of whom, Wolf Tone, Hamilton Rowan, and James Napper Tandy, were forced to expatriate themselves, changed at once to a system of conciliation. In assurance of the sincerity of the change of sentiment, Earl Fitzwilliam, a nobleman possessed of large estates in Ireland, and a steady advocate of liberal measures, was sent over as lord-lieutenant. He commenced his government by arrangements for bringing in a bill for the total repeal of the penal statutes, and by the removal from office of the inferior agents of government, who, by their long continuance in place, and the manner in which their mutual interests were connected, virtually possessed the supreme power. The latter of these efforts caused the lord-lieutenant's removal. The family of the Beresfords, which had for many years possessed the chief places of profit and influence, remonstrated effectually against their own dismission and the breaking up of the old system, and Earl Fitzwilliam was suddenly recalled. Earl Camden, who succeeded him as lord-lieutenant, recurred to the former system of patronage and coercion. The United Irishmen now looked not to a reform, but to a separation from Great Britain, and the establishment of an independent republic in alliance with that of France, as the only means of securing the independence of their country. A well-arranged system of secret confederacy was spread over the greater part of the kingdom, headed by an executive in the capital, the members of which, though wholly unknown, except to the few individuals in immediate communication with themselves, issued orders for enlisting, combining, and arming their adherents, which were zealously and implicitly obeyed. The northern and midland counties had for some time been disturbed by the fierce and deadly contentions of the peasantry of the two opposite religious creeds; the Catholics took the name of Defenders, the Protestants that of Orangemen. As the struggle grew more desperate, the attraction of party extended to the higher classes, and the former of these predial disturbers merged into the great mass of United Irishmen, whilst the latter, consolidated by the infusion of a superior spirit of wealth and intelligence, formed a compact, well-organized, and resolute body, under the original name of Orangemen, determined to maintain to the utmost their own monopoly of power, and the entire exclusion of the Roman Catholics, who formed the great mass of the population, from any participation of it. The increasing hostility of both parties showed itself by acts of augmented atrocity on both sides. The Defenders' means of aggression were nocturnal plunder, house-burnings, and murders. The other party, backed by the sanction of the government, had recourse to the force of statutes of increased rigour, and, where these failed, to the agency of military violence beyond the law. In the year 1796 the organization of the united system on the one side, and on the other the increased severities of the Orangemen, supported by the government, and directed exclusively against the Catholic peasantry, compelled the leaders of the people to press upon the French government the necessity of an immediate invasion. In consequence of their repeated and urgent applications, aided by the exertions of Wolf Tone, who, since his departure from Ireland, had devoted himself to this object, a large armament was equipped in the western ports of France, for the avowed purpose of invading Ireland. The command of it was intrusted to Hoche, then considered as the first officer of the time. Taking advantage of a storm which drove the blockading squadron of England off the coast, a large fleet sailed from Brest under his command in the middle of December; but the same violence of weather which afforded it the opportunity of eluding the vigilance of the British navy dispersed it when at sea, insomuch that but a part of the armament arrived on the coast of Ireland. Having lain for some time in Bantry Bay undiscovered by the enemy, waiting the arrival of the general, who had embarked in a frigate, and finding the further continuance on the station every day more precarious, it departed, contrary to the pressing remonstrances of Wolf Tone, and returned to Brest, whither the remainder of the fleet soon afterwards arrived, with the loss of a few ships. A second expedition from the Dutch coast was equally unsuccessful. The possibility of an invasion being thus demonstrated, and the probability of its ultimate success, if effected on a great scale, being apprehended in the present excited state of the public mind, the government had recourse to still stronger measures to put down the spirit of insurrection. The habeas corpus act was suspended, domiciliary visits throughout the country parts were frequent, meetings of the people were dispersed by violence, torture was inflicted to force confession from suspected persons, and bodies of soldiery were allowed to live at free quarters in suspected districts. The relaxation of discipline and consequent outrages arising from these practices caused General Abercromby, who came over to take the command of the army at this juncture, to declare, in general orders to the troops, that "the army was in a state of licentiousness which rendered it formidable to every one but the enemy." The announcement was as unpalatable as it was harsh. The general was recalled. General Lake was sent in his place. By his commands the soldiery exercised an almost uncontrolled authority, in which they were sanctioned by instructions from the government empowering the army to use force at the discretion of the officers against the people. At the same time the strength of the United Irish Association was considerably impaired by the arrest or flight of the executive, caused by the treachery of some of their own body. This circumstance, however, produced no despondency. On the contrary, it led to increased exertion. A new executive was formed, and a resolution adopted to press forward the insurrection without waiting for French assistance. A second act of treachery baffled this effort. Twelve of the leading members of the United Irishmen were seized, with their papers, whilst in committee. A third act of treachery led to the disclosure of the details of the plans. Captain Armstrong, of the king's county militia, entered the association for the purpose of betraying its leaders. By his information two barristers of the name of Sheares, brothers, were arrested; and shortly afterwards, Lord Edward Fitzgerald, a brother of the Duke of Leinster, to whom the chief command of the insurrection had been intrusted, was seized in his place of concealment in Dublin, and carried to prison, where he soon after died either of his wounds or from his treatment whilst there. Notwithstanding these checks, the insurrection exploded at the time arranged by its leaders. On the evening of the 23d of May, the United Irishmen assembled in large bodies in the neighbourhood of Dublin and the adjoining counties. The warnings previously given to government were sufficient to provide against the intended attack upon the capital. The parties collected in its neighbourhood were easily dispersed, with the loss only of a few lives. Unfortunately the same vigilance did not extend to the more distant parts. The signal for commencing operations on the side of the insurgents was to be the non-arrival of the mail coaches at their respective places of destination. The northern and western mail coaches were stopped. The town of Naas was attacked, but, owing to an anonymous warning, the garrison was prepared, and the assault was repelled. Unsuccessful attacks were also made on Carlow, Hacketstown, and Monasterevan. A large body which had assembled on the hill of Tarah was routed with much slaughter. The operations of the army were seconded by the most violent acts on the part of the government. Several of the leaders who had been previously seized were tried and executed. Numbers arrested on suspicion were brought to places prepared for the purpose, and there tied up and flogged, to extort confession. The principal places in Dublin for these inquisitorial executions were the Royal Exchange, the Old Custom-House, the Prevot Barrack, and a riding house belonging to a cavalry corps commanded by one of the Beresford family. The atrocities practised in the capital under the sanction of the government were improved upon in the country parts, where the military, to whom full license was permitted, by putting the country under martial law, not only adopted the same method of extorting confession, but used others of more refined agony to elicit discoveries or to gratify revenge. In some cases they hanged up their victim, and let him down again just before life was extinct; thus repeating at pleasure the sufferings of strangulation. On the heads of others they applied caps lined with heated pitch, which, when fastened on, and allowed to cool, were suddenly torn off, carrying with them the hair and skin. In the spirit of fiendish mockery, they cut ridges in the hair of others, in the form of a cross, and filling up the furrow with gunpowder, set fire to it. On the first breaking out of the rebellion, a number of suspected persons, some of them respectable farmers, who had been confined in a racket-court at Hacketstown, were deliberately shot, without even the form of trial, on the removal of the troops from that place, lest they should join the rebel camps. A similar massacre was perpetrated at Dunlavin. The insurgents of Kildare, finding themselves defeated in almost every assault upon the king's troops, came forward to surrender on promise of pardon. Many laid down their arms, and were permitted to disperse in safety. But a large body of them, assembled for the same purpose, was unexpectedly attacked by a detachment of the military, who had not been made acquainted with the arrangement, and cut to pieces.

The system of torture was carried by the soldiery into the county of Wexford, which had hitherto remained quiet.

Here the insurgents were more successful. After cutting to pieces a detachment of cavalry from Dublin, and another of infantry and artillery from Duncannon Fort, and taking Enniscorthy by storm, they seized on the town of Wexford, which had been evacuated on the first alarm by the military. Having established themselves here, and at Vinegar Hill, an eminence near Enniscorthy, they remained comparatively quiet, being chiefly occupied in putting to death prisoners charged with having been active in the cruelties practised upon the insurgents. Their first serious defeat was at New Ross, from which they were repulsed after a sanguinary contest of ten hours. In revenge for this defeat, a party of the fugitives set fire to a barn at Scullabogue, in which upwards of an hundred of their prisoners were confined, all of whom were either burned, or piked in attempting to escape from the flames. The same impulse of sanguinary despair caused the insurgents in Wexford to put their prisoners to death, by piking them on the bridge, and flinging their bodies into the sea; a process of cruelty continued for several days, notwithstanding the active interference and remonstrances of several of their own clergy. At length, however, their main position at Vinegar Hill was invested by a large military force, and stormed after a short resistance. Wexford soon afterwards fell into the hands of the royal troops, having surrendered without resistance, on conditions which were immediately violated. The leaders of the insurrection who had not fallen in the field were executed by court-martial, and the insurrection in this and the neighbouring county of Wicklow totally suppressed.

The news of the first successes of the insurgents in Wexford caused a rising in the counties of Antrim and Down, which had remained passive on the first breaking out of the insurrection in Kildare. But it was speedily put down after a battle in the town of Antrim, and another at Ballynahinch, in both of which the insurgents, who displayed much courage, but no military skill, were totally defeated. The marauding parties, who still harassed the country after the dispersion of the main bodies, were ultimately broken up by the prudent and merciful conduct of Lord Cornwallis. This nobleman, who succeeded Earl Camden as lord-lieutenant, not only put an instant stop to the system of torture and extermination which had been adopted and perseveringly acted on by his predecessor, but issued an amnesty to all who submitted and returned to their dwellings. This merciful policy had its full effect; and the country, after being convulsed for two months by the deadly struggles of the contending parties, entertained the hope of being restored to tranquillity, when the prospect was suddenly overcast. Towards the close of summer, a small French squadron landed a force of about twelve hundred men at Killala, in the west of Ireland. Humbert, the general, being joined by a number of the inhabitants, pressed on to Castlebar, where a force of from five to six thousand men under General Lake was posted to oppose him. This force was taken by surprise, and routed almost without firing a shot. The French then proceeded to Coolooney, where they received a temporary check from a party of the Irish militia, which made a gallant stand against superior numbers; and thence proceeded, followed by General Lake, into the county of Longford. Having arrived at the village of Ballynamuck, the French commander, finding himself surrounded by an overwhelming majority of force, collected from all parts by Lord Cornwallis, surrendered at discretion, leaving his Irish auxiliaries to the mercy of the enemy. No quarter was given to these. A second attempt at invasion, equally feeble and futile, was made the following month. A small squadron appeared off the northern coast, filled with troops intended for disembarkation; but it was routed by a superior English fleet, with the loss of one line-of-battle ship and six frigates, in which were some of the expatriated Irish who were embarked in this desperate expedition. Amongst these was Wolfe Tone, who, on being brought prisoner to Dublin, anticipated the sentence of a court-martial by an act of suicide.

The explosion of the insurrection hastened on the steps for effecting a legislative union, long a favourite measure with the British minister. The intention was announced in the lord-lieutenant's speech at the opening of the parliament in 1799. After a discussion of upwards of twenty-four hours in the lower house, a resolution approving of the principle was carried by two voices, a majority so small that it was viewed on both sides as tantamount to a rejection of the question. In a subsequent debate the opinion of the house was more expressly declared against it by a majority of five. The public discussion of the subject being thus suspended by this expression of a majority of the representatives of the people, the Irish government employed itself for a renewal of the effort, by bringing into action every means of intimidation and influence at its command. Public meetings convened to express sentiments adverse to a closer connection with Great Britain, were either prevented or dispersed by military authority; tenders of honours and emoluments were lavished upon all who possessed the means of influencing the votes of members of the House of Commons. The great body of the people were induced to give the measure a tacit though reluctant assent, from a promise held out to them of Catholic emancipation as its result. Confiding in the success of these arrangements, Lord Castlereagh, the Irish minister, revived the question early next session; and, on a division, found himself at the head of a majority of forty-two, notwithstanding the violent and impassioned exertions of all adverse to the measure, which proceeded even to a hostile collision between two of the leaders of the contending parties, Mr Grattan, and Mr Corry, the new chancellor of the exchequer, the latter of whom was wounded on the occasion. The principle being thus admitted, the details were easily arranged, as they had been settled by the British parliament during the late session; so that at the close of the year the two separate parliaments of Great Britain and Ireland were dissolved, never to meet again, and a proclamation issued for the assembling of an imperial parliament in January 1801. The principal articles of this international treaty are,—1. The permanent union of the two kingdoms into one, under the name of the United Kingdom of Great Britain and Ireland. 2. The succession to the throne to continue limited as at present. 3. The kingdom to be represented by one parliament, to be called the Parliament of the United Kingdom of Great Britain and Ireland. 4. Twenty-eight peers temporal elected for life, and four spiritual peers succeeding each other by a rotation of sessions, were admitted into the House of Lords; one hundred representatives, two for each county, two for Dublin city, two for Cork city, and one each for thirty-one towns and the university, were to be elected into the lower house. 5. The churches of England and Ireland were to be united into one, to be called the United Church of England and Ireland, the doctrine, worship, and discipline of which was to be the same as that established for the Church of England. 6. The subjects of Great Britain and Ireland were to be placed on the same footing as to manufactures, trade, and commerce. 7. The contribution of each portion of the empire towards the general expenditure was to be in the proportion of fifteen to two between Great Britain and Ireland for twenty years; after which, to be regulated at the discretion of parliament. 8. The existing laws and courts of justice in each island were to continue as heretofore, except that appeals from the Irish chancery were to be brought before the House of Lords in England.

History. The style of the king was in consequence changed to that of king of the United Kingdom of Great Britain and Ireland, and the blazoning of the royal standard was altered accordingly.

The act of union, after it had been carried by an unprecedented combination of corruption and intimidation, did not at once produce the results promised by its advocates. It neither tranquillized the country, nor aided the consolidation of its resources. The Protestants, who constitute the aristocracy, found their influence diminished by it. The Catholics soon discovered the hopelessness of the expectation of being thereby admitted to the rights of freemen. When the question of their emancipation was about to be made an object of discussion, it was now for the first time publicly announced that the king had insuperable objections to the measure. The consequence was a change of ministry, which was followed up by legislative measures of great severity towards Ireland, founded on a suspected apprehension of the existence of a secret spirit of disaffection there. Martial law was re-enacted, and the acts for the suspension of the habeas corpus, and for preventing seditious meetings, were revived. These measures of prospective severity did not prevent the mischiefs apprehended. In 1803, less than three years after the passing of the act, an insurrection, devised and matured by a gentleman of the name of Robert Emmett, the younger brother of a barrister of the same name who had expatriated himself in consequence of the leading part he had taken in the proceedings of the United Irishmen, broke out in the city of Dublin. Its explosion was so sudden and unexpected, that no suspicions, at least none strong enough to lead to the adoption of measures of precaution, were entertained by the government. Soon after sunset on the 23d of July, Mr Emmett, at the head of a number of his followers, armed chiefly with pikes, issued from a depôt established by him in an obscure street in the west of Dublin, and after cutting down some of the military who were proceeding individually to their several quarters, moved towards the Castle, the main object of attack, when his followers were delayed by the approach of Lord Kilwarden's carriage. This nobleman, who had been chief justice of the King's Bench during the late troublous times, was coming into Dublin as a place of security, in consequence of a rumour of a rising having reached him in his villa, a few miles from town. On being recognised, he was immediately assailed, mortally wounded, and lingered only about two hours. His last words were, an entreaty that none engaged in the insurrection should be put to death without trial. His daughter and his nephew accompanied him in his carriage; the latter was killed on the spot, the former was allowed to pass unmolested through the crowd, every one exclaiming that the lady must be spared. The arrival of two small piquets immediately dispersed the collected multitude, with the loss of a few lives. Emmett, on finding the failure of his scheme, escaped to the neighbouring mountains, where he was soon afterwards taken, brought to trial, and executed. Thus died a young man of good family, superior talents, and enthusiastic zeal for the independence of his country, through a deplorable error of judgment, in endeavouring to attain an object in itself so honourable, by means totally inadequate to its magnitude, and attainable through a frightful expenditure of human life. A similar attempt at insurrection was arranged in the north of Ireland by an associate of Emmett, of the name of Russell. It was discovered before the time fixed for its explosion. Measures of prevention were adopted, and its leader, being soon afterwards taken in his place of concealment in Dublin, was also executed. The whole transaction was but the act of an hour; its only permanent consequence the revival of statutes of extreme severity, which, by placing the people beyond the protection of the usual course of law, served to foster in the mind the seeds of discontent and disaffection, which it was the professed object of such legislation to extinguish.

The agitation of the feelings of mutual irritation between the two great parties in Ireland, arising from the late insurrection, had not sufficiently subsided to admit of the most distant hope that the Catholic claims would receive the slightest attention in parliament until 1805. Even then, so powerful was the party adverse to the entertaining of the question in any manner, that motions for a committee on the petitions of the Catholics presented in that year were rejected in both houses by overwhelming majorities. Even a bill, which asked no more than to put Roman Catholic officers in the army on the same footing in the English as they were in the Irish service, brought in by the then ministry, led to a dissolution, both of the administration and of the parliament, in consequence of the king's aversion to it. For several years afterwards, the question was periodically mooted in one or both houses of parliament, and uniformly rejected, though on each subsequent occasion by a diminished majority against it. In 1811, so little were the rights of conscience respected, so little regard was paid to the religious feelings of Catholics, that soldiers of that persuasion were sentenced to do duty with their coats turned, in consequence of having attended at the public worship of their own church. The effect of the punishment was directly the reverse of that intended. Such a wanton insult on the feelings of the great body of the people excited universal disapprobation, and an order was issued, not merely to permit the Catholic soldiery to be present at their own places of worship, but to take care that they should proceed thither in military order.

The Catholic committee, which had sat under various names and forms from time to time ever since its original institution in 1756, having, in 1811, proposed to assemble by delegation in Dublin, steps were taken by the government to put it down, as being contrary to the convention act, which prohibited such assemblages, and one of the members, Dr Shendan, was prosecuted; but, in consequence of his acquittal by a Dublin jury, no further proceedings were then taken. About the same period the exacerbation between the members of the two great parties, the Orangemen on one side, and the Catholics on the other, led to frequent personal collisions among the lower classes, which terminated in bloodshed in several places. In 1817 public opinion had advanced in favour of the Catholic claims so far as to admit of the question of securities being a topic of discussion both in and out of parliament. The royal exertion of a veto in the nomination of the Catholic hierarchy was now the great point. A letter on the subject from M. Quarantotti, president of the sacred missions at Rome, to Dr Poynter in England, in favour of it, excited much controversy. The general feeling of the Catholics of Ireland against any ministerial interference with the ministers of their religion was decisive and strongly marked. The question therefore was dropped.

During these protracted and angry discussions, it was not to be expected that the internal prosperity of the country could have increased. On the contrary, the sanguine anticipations of the advocates of the union, as to its good effects on the great interests of Ireland, were so far from being realized, that, in 1817, the public debt of the country had increased to such a magnitude as to threaten a national bankruptcy, which was averted only by the consolidation of the exchequers of the two great parts of the empire; Great Britain thus being made responsible, if not for the discharge of the principal, at least for the regular payment of the interest, of the Irish debt. Three years afterwards, the failure of ten private banking-houses, one in

Dublin, and the others in the south and west, caused a general stagnation of trade. The greatest distress among the working classes was the consequence. In 1821 the king (George IV.) proposed to visit Ireland, with the view, as was universally understood, of establishing, by his personal interference, a bond of amicable relations between all classes of Irishmen. He landed on his birth-day, was enthusiastically received, entered Dublin with a splendid retinue, visited all the public institutions, conferred some honours, and, after a visit of about six weeks, spent partly in the metropolis, partly at the mansion of the Marquis of Conyngham, in the county of Meath, he quitted the country, as he had entered it, amidst the acclamations of congregated thousands. Previously to his departure, a letter was issued by his order, expressive of his gratification at the reception he had met with, and of his desire of the mutual good will of his subjects. But his visit effected nothing. The remedy was too superficial, too evanescent, to effect a cure; the cause of irritation remained still untouched, rankling in the heart's core of the community. Shortly after his departure, the feud that had been lulled by respect and expectation broke out anew. Catholics and Orangemen were again opposed to each other. The insurrection act was again called for, and granted. In 1822, the failure of the crops produced a state of destitution truly appalling. It was relieved by the generous exertions of the people of Great Britain, who, when informed of the exigency of the case, through the instrumentality of Mr J. Smith, a London banker, and member of parliament, came forward with a liberality of contribution, which, aided by the efforts of the government, thus directed to the knowledge of the existence of an evil that it ought to have foreseen, checked the consequences of extreme famine.

In 1823 the Catholic question began to assume a new and more imposing form. Its change of character was owing to Mr Daniel O'Connell, a barrister, who, after having signalized himself on his first entrance into political life by his energetic and eloquent protest against the extinction of the parliament of Ireland, had been subsequently an active and most influential actor in all the proceedings of the Catholic body. Deploring, alongst with his friend and coadjutor in political action Mr Shiel, the state of torpid depression in which the question now seemed sunk, he suggested the revival of a central body to advocate and manage their cause, planned its details, and commenced its organization. The first meeting of this body, so soon, under the name of the Catholic Association, to be the acknowledged organ of the public sentiment of the greater part of the population of Ireland, commenced in a meeting of three individuals, of whom O'Connell himself and Sheil were two. Its distinguishing characteristics were the exclusion of any thing savouring of delegation, a strict adherence to the letter of any law that had been or might be enacted in order to stifle the expression of the sentiments of the Catholics, and, above all, the admission of the great body of the people into it. This last element of its constitution was finally secured and firmly grafted into it, after a precarious struggle for existence for some time, by a pecuniary contribution, which Mr O'Connell, its inventor, as sagaciously as quaintly denominated "the Catholic rent." By this every Catholic was called upon to subscribe at least one penny per month to defray the expenses of the association, and thereby became a member of it. These expenses were far from inconsiderable. They were applied partly to protect poor Catholics from the petty persecutions of intolerant magistrates and landlords, partly to meet the general expenditure of the association, whose communications with all parts of the country could not otherwise be effectively carried on, and partly for the gratuitous circulation, throughout every part, of a newspaper, containing a detail of all the proceedings and debates of the association. Opportunities soon presented themselves of displaying the powers of the organization thus devised. The first was the consequence of an act passed for its suppression, which, from its severity, was nick-named "the Algerine act." Its operation was so parried by the ingenious management of the association, as to render it ineffective, and the association continued to meet in open submission to its provisions, but in virtual defiance of them. The second was, if not more effective, certainly more imposing. The county of Waterford had for more than seventy years been represented by a member of the Beresford family. On the dissolution of parliament in 1826, the Catholic, or as they now began to style themselves, the liberal party, resolved to throw off the yoke to which they had tamely submitted for nearly a century, and to send into parliament a representative of their own choice, without regard to any accustomed rules of family claims or rights of landlords. Mr Stewart, a young gentleman of large fortune, then travelling on the Continent, was invited to stand as candidate. He obeyed the call, and in a few weeks arrived in Waterford. The preparations for a contest were at first disbelieved or derided by the county aristocracy. So far were the landlords from an apprehension of a disruption of the old bond by which they heretofore held their tenantry engaged to obey their dictates in the choice of a representative, that the Duke of Devonshire, who, though, as a liberal, he would not openly take part with the Beresfords, yet wished to maintain the long-established custom of the tenants' subserviency, declared, that "though, from respect to the constitutional rights of the people, he refused as a peer to interfere with the votes of his fifty-pound freeholders, he expected *of course* that his forty-shilling freeholders would abstain from giving their votes to either of the rival candidates." His dictation was to no purpose. When the day of election arrived, his as well as all the other Catholic tenantry voted for the new candidate, so that at the close of the fifth day's poll the brother of the Marquis of Waterford, hitherto the undisputed nominee of the family, relinquished the contest in despair. The example of Waterford was followed in Louth, Monaghan, and Westmeath, in each of which counties popular feeling triumphed over family influence in the choice of a representative.

The dissolution of Mr Canning's ministry by the unexpected death of its leader, and the formation of that of the Duke of Wellington, gave a character of increased energy to the Catholic struggle. Mr Canning had appointed the Marquis of Anglesey to be lord-lieutenant. The sentiments of this nobleman upon the Catholic question were little known; but the apprehensions of his hostility entertained by many on his first arrival were quickly dissipated. The association was not suppressed, coercive statutes were not called for; the people were suffered to discuss and to petition without official interruption, as long as they restrained themselves within the limits prescribed by law. On the Duke of Wellington's succession to power, he was universally believed to be decidedly and irreclaimably adverse to concession. One of the first measures then taken by the Catholics, was the adoption of pledges to be given by every candidate, on an election, to oppose his administration. These pledges were intended for the next general election. An earlier opportunity of trying their efficacy presented itself. A vacancy was occasioned in the representation of Clare, by one of the county representatives, Mr Vesey Fitzgerald, accepting a place in the cabinet. Mr Fitzgerald had always been an advocate for Catholic emancipation; he was a resident landed proprietor, of amiable manners; and his father had resigned a lucrative post at the bar rather than vote against the feelings of the country on the question of the union. But he was the nominee of the Duke of Wellington, the reputed enemy of the Catholics. He therefore came within the mean-

History. ing of the pledges, and was to be rejected if the Catholic power in Clare was sufficient for the effort. A new difficulty presented itself. The candidate chosen by the people refused to stand in opposition to Mr Fitzgerald. The day of election was hastening on. No other suitable resident was to be found to supply his place. In this emergency Mr O'Connell, the leader of the Catholic body, the founder of the Catholic Association, stood forward and offered himself. The result was the same as at Waterford. The election terminated in an overwhelming yet peaceful triumph. Mr O'Connell was the acknowledged representative of the county of Clare, the first Catholic returned to sit in the imperial parliament of Great Britain.

For some time previous to this event, the Orange or anti-catholic party, alarmed at the rapid progress of their antagonists, and the high position they were on the point of attaining, had banded themselves into a new system of counter-association, under the name of Brunswick Clubs, the avowed object of which was to resist any further concessions to the Catholics. Both parties now every day presented more and more the aspect of uncompromising hostility. Their speeches assumed the character of mutual denunciation. The arm of each was all but lifted up. Each seemed to wait only that his antagonist might strike the first blow, and be the first to outstep the bounds of constitutional resistance. In this awful pause, the liberal Protestants, who had hitherto advocated, mildly, if not timidly, the cause of the Catholics, felt that their own safety and that of their common country required more decided measures. Mr John David Latouche, a banker in Dublin, the head of a family long known and respected for extensive benevolence and liberal political sentiments, prepared a declaration expressive of the necessity of parliament taking the whole subject into its immediate consideration, with a view to its final and conciliatory adjustment. Copies of this declaration were circulated throughout all parts, and in a singularly short period it received the signatures of sixty-nine peers, either Irish, or holders of large properties in Ireland, and upwards of two thousand other landed proprietors. At this crisis the Marquis of Anglesey was suddenly and angrily recalled, in consequence, as was universally believed, of his recommendation to the Catholics, expressed in a letter to their primate, of peaceful but determined perseverance in the pursuit of their rights. An impression now prevailed amongst parties that this act was decisive as to the Duke of Wellington's determination to resist all concession. The Brunswick Club held its meeting in Dublin. Its bearing was that of boldness and defiance. The liberal Protestants, who had as yet assumed no specific title of recognition, determined on an antagonist meeting. It was held in January, and was even more numerously attended than its most zealous devisers had anticipated. Petitions to the king and both houses of parliament for the total repeal of all the laws disqualifying the Catholics were adopted; and the basis was laid for the formation of a society of united Protestants and Catholics, for the attainment of civil and religious liberty, under the name of the Irish Association. The unexpected change in the measures of the king's government towards Ireland rendered any further progress in these projected plans unnecessary. The Catholic emancipation bill passed on the 13th of April 1829, clogged indeed with two provisos not quite in unison with the spirit of liberality that marked its main enactments. The one was general in its object, the disfranchisement of the forty-shilling freeholders; the other was personal, excluding Mr O'Connell, not by name, but virtually, from the seat to which he had been nominated at the late Clare election. The latter exception proved altogether futile. Mr O'Connell was again returned at the next election. The attainment of Catholic emancipation was followed by a loud though not universal demand for the repeal of the legislative union, and for the abolition of tithes; an impost considered as degrading in principle, as it was felt to be oppressive in the mode in which it was levied. The reform question also was added to the number of stimulants of the public mind. This last-named subject of irritation has been laid at rest in a manner not so satisfactory to Ireland as to the other great divisions of the empire, but so as to lead to reasonable hopes of its progressive efficacy. The question of repeal has been silenced as far as can be done by an authoritative declaration of one, and that one the more powerful, of the parties interested in its decision; the tithes still remain a question, no longer of Irish, but of imperial interest.

STATISTICS.

Statistics.

Dimensions. The island of Ireland is of a rhomboidal shape, having its longer sides nearly in the direction of the meridian, and its shorter from south-west to north-east. It lies between the latitudes of 51. 26. and 55. 20. north, and the longitudes of 5. 28. and 10. 28. west. In the direction of its greater diagonal, from Browhead in the south to Fairhead in the north-east, it measures 306 miles. Its extreme length, from its most southern point, already named, to Walinhead, its most northern extremity, is 290 miles; its greatest length on a meridian 235 miles. Its breadth where greatest, measured from Emlagh-rash, in the peninsula of the Mullet, to Killard Point, at the entrance of Strangford Lough, is 182 miles; but its least breadth, from the eastern side of Galway Bay, near Oranmore, to Ringsend, near Dublin, is not more than 110 miles. The whole comprises an area of 20,499,550 acres, or 320,312 statute miles. Separated from the adjacent island of Great Britain by an arm of the sea not more than forty-nine miles across at its southern extremity, and narrowing to twelve miles at the north, but expanding in its intermediate space into the Irish Sea, it is washed on its three other sides by the Atlantic Ocean, whose waves have indented its western and southern shores with many large bays and inlets, trenching far into the country; so that the whole outline of the coast, including that of the estuaries of the great rivers, to the boundary of the tide, is estimated to measure upwards of 2200 miles. Boundaries.

Coasts. This extended line contains a great number of fine harbours and roadsteads. The eastern coast has but one; that of Strangford or Lough Cone, which forms a very deep bay, with sufficient depth of water for every kind of ship. The bays of Carrickfergus, Dundalk, and Carlingford, are adapted only for vessels of lesser draught; Dublin is so defective as to require the construction of two safety harbours; one to the north, at Howth, and the other to the south, at Kingstown. The coast to the south of Dublin affords no shelter for large ships; Wicklow, Arklow, and Wexford, admitting only vessels of very small size. This part of the coast is also dangerous, from the shoals which extend along it near the land. On the southern side of the island is the fine estuary of Waterford, formed by the confluence of the Suir, Nore, and Barrow. Here ships of large burden can discharge at the quay of Waterford. Farther on is Cork Harbour, securely land-locked and protected by large batteries, and therefore chosen as the principal naval station on the Irish coast in time of war. Still farther are Baltimore Harbour, Long Island, Skull, Cape Clear, Crookhaven, Dunmanus, and Bantry Bay, all of sufficient depth and capacity for the largest ships. A French fleet, designed for the invasion of Ireland, lay in the last named of these in the winter of 1796. Turning westward are Berehaven, Quoylagh Bay, Kenmare River, and Kilmichalog and Sneem Harbours, Valen-

Statistics. tia, Ventry, Smerwick, and Brandon Bay. The estuary of the Shannon contains several good stations. Farther north is Galway Bay, also containing several smaller ones; Casheen, Kilkerran, and Roundstone Bays, the last of which is capable of containing the whole navy of Britain; Birter Bay, Ardbear or Clifden, Cleggan Bay, Ballynakill and Killery Harbours; Clew Bay, within which a numerous archipelago of islets affords many safe stations. Proceeding still in a northern direction is Blacksod Bay, Broadhaven, Killala Bay, Killibegs Harbour, and Macswine's Bay. On the northern coast are Milroy Harbour, and the two fine gulfs of Lough Swilly and Lough Foyle. The harbours and inlets for the reception of smaller vessels are too numerous to admit of detailed enumeration. In short, there are upwards of seventy harbours well suited for the general purposes of commerce, and fourteen capable of accommodating large naval armaments.

Islands. The islands near the shore are numerous, but few of large size. Their total number is nearly an hundred and fifty. Amongst the most remarkable are, on the north shore, Rathlin or Raghery, celebrated for its basaltic formation; Tory, Ennisbofin, and the Rosses, the largest of which is Arranmore. On the west, Enniskea, Achill, Clare, Ennisbofin, the southern islands of Arran at the entrance of Galway Bay, the Blasquets, and Valentia. On the south are Bear and Whiddy in Bantry Bay; Cape Clear, long supposed to be the most southern point of Ireland; and Cove Island, in Cork Harbour. The few islets on the eastern coast are uninhabited, except one. The most remarkable of these are, Dalkey, Ireland's Eye, Lambay, the Skerries on the coast of Dublin, and the Coplands at the entrance of Carrickfergus Bay. The population of all the coast islands is estimated at 43,000 souls. They are thus classed as to provinces.

Provinces.	Total Number.	Inhabited.	Population.
Leinster..........	6	1	34
Ulster............	40	27	4,546
Munster..........	70	50	22,827
Connaught.......	80	60	15,592
	196	138	42,999

Surface. The surface of the country is, generally speaking, plain, yet not altogether level, but rising in most parts into hills of small elevation. The most level parts are in the centre, in a band extending across the island from Dublin to Galway, in which the land rises gradually from the coast, to a height of 322 feet. The hill of Moat-a-Grenogue, in Westmeath, is the highest point of the plain. Both in the north and south the land rises into heights much greater, but none of such elevation as to retain the snow during any long period of the year; the most elevated point in Ireland not attaining to the range of 3500 feet above the

Mountains. level of high water. The mountains form groups rather than chains. The highest is in the west of Munster, the next in height in Leinster, the third in Ulster, and the fourth in Connaught. All are near the coast. The comparative altitudes of the highest points in each group are as follows:

Munster,	S. W.	M'Gillicuddy's Reeks, Kerry....	3410
		Mangerton, Kerry..................	2693
Leinster,	S. E.	Lugnaquilla, Wicklow............	3070
		Thonalagee, Wicklow.............	2696
Ulster,	N. E.	Slieve Donard, Down.............	2809
Connaught,	N. W.	Muilrea, Mayo.......................	2737
		Croaghpatrick, Mayo..............	2660
		Nephin, Mayo.........................	2630
		Furmnagur, Mayo..................	2569

Rivers. The largest river is the Shannon, which, rising in the mountains in the confines of Fermanagh and Leitrim, flows through Lough Allen, and thence in a south-western direction, separating Connaught from Leinster, till, arriving at Limerick, it turns westward, and discharges itself into the Atlantic, through a fine estuary, which, at its entrance between the capes of Loophead and Kerryhead, is eight miles wide. It is navigable for large vessels to Limerick, near which its course is checked by natural obstacles. During its passage from Lough Allen to Limerick it expands into the large lakes of Lough Reagh, fifteen miles, and Lough Dearg, twenty-one miles, in length. Each of these is narrow, and studded with numerous islets. The Blackwater rises near Charleville, and, flowing south-eastwards, discharges itself into the Atlantic at Youghal, after forming the boundary between the counties of Cork and Waterford. Between the latter county and that of Wexford is the estuary of the Suir, the Nore, and the Barrow, all of which have their sources not far from each other in the central range of the Slievebloom Mountains; and, after diverging so that their streams enrich a great portion of the provinces of Leinster and Munster, unite again near the city of Waterford. The Slaney rises in the mountains of Wicklow, and empties itself into St George's Channel at Wexford. The Boyne, famous for its historical recollections as well as for its natural advantages, has its sources in the central elevated plain of Leinster, and, flowing north-eastwards, falls into the Irish Sea at Drogheda. The Bann rises in the Mourne Mountains, flows northwards through Lough Neagh, and, after separating the counties of Londonderry and Antrim, flows into the Atlantic at Coleraine. The Foyle is formed by the union of the streams of the Poe, the Mourne, the Finn, and the Derg, which, flowing from different parts of the interior of Ulster, discharge their combined waters into Lough Foyle near Londonderry. The Erne, which gives vent to the waters of Lough Erne, has a short course to the Atlantic westwards, checked by several ridges of rock, which form fine falls. The other rivers, though numerous, amounting nearly to an hundred, are small, and mostly confined to the counties that give them birth. The Liffey, which rises in the mountain-land of Wicklow, and, after a circuitous course through Kildare, discharges itself into the Irish Sea, is remarkable for little more than that Dublin city, the metropolis of the island, is seated on its banks.

Lakes. The lakes are numerous. Lough Neagh, in Ulster, is the largest. It covers 97,272 acres at high-water mark. The river Bann passing through it affords the means of lowering its surface, if such a process should be deemed advisable; but as its lowest part is beneath the level of low water, its total drainage would be impracticable. Tradition states that it was once dry land; and the boatmen assert that the tops of buildings may at times be seen in it. It contains but one islet, Ram Island, remarkable only for a round tower. Its vicinity to five of the most agricultural and manufacturing counties of Ulster, Antrim, Down, Armagh, Tyrone, and Londonderry, each of which its waters touch, present great advantages for internal trade by inland navigation. This lake has long been celebrated for its petrifying qualities, by which trunks of trees have been converted into a siliceous substance. Lough Erne, the next in size, lies wholly within the county of Fermanagh. Its total length is upwards of forty miles, but its greatest breadth is not more than eight. Strictly speaking, it consists of two lakes; the more inland measuring about fourteen miles in length, and that nearer the sea twenty-five. They are connected with one another by a narrow channel, on which the town of Enniskillen is built. Its area covers 48,797 acres, and it is adorned with upwards of an hundred islets. The level of its waters is 140 feet

Statistics. above the sea. Its coasts are studded with numerous seats and villas of much beauty. Lough Corrib and Lough Mask, in the west of Connaught, are separated from each other by an isthmus not more than three miles broad. The former of these lakes is thirty miles long, and from nine to ten broad in some places. It discharges its waters into Galway Bay by a short but broad and rapid river, which skirts the town of Galway. Though its level is but fourteen feet above that of the sea, the means of connecting them by water communication has not yet been effected. Lough Mask is of smaller dimensions, and has attached to it Lough Gara, still more diminutive. Farther north is the narrow lake of Lough Conn, fourteen miles long. The other lakes are too numerous, and not of sufficient importance as to size or local peculiarity, to admit of a detailed description. Most of them lie in the central plain, particularly in the counties of Cavan, Westmeath, and Longford. From this sweeping exclusion a few must, however, be excepted. Lough Lane, or the Lake of Killarney, in Kerry, has long been celebrated for its picturesque scenery. The tract of water distinguished by this name consists of three parts, connected by short straits. Lough Derg, in the south of Donegal, is small, but of great celebrity from an islet in it called St Patrick's Purgatory, which has been resorted to from time immemorial as a place of penance by pilgrims of the Roman Catholic persuasion. Several attempts have been made to put an end to the religious ceremonies performed there, but without success. It still continues to be visited by multitudes of strangers from all parts, from a reliance on its supernatural qualities. This lake is not to be confounded with the Lough Dearg already noticed as lying on the course of the Shannon. Lough Gill in Sligo, Lough Shellin to the north of Meath, and Lough Oughter in Cavan, are also worthy of notice for their scenic beauties.

Forests. Ireland was once so thickly covered with timber as to receive the name of the Island of Woods. During the early periods of its connection with England, its extensive and impenetrable forests formed a main obstacle to the progress of the English troops. Westminster Hall is said to be roofed with oak cut in the woods of Shillelagh. Numerous trunks of large trees are constantly found in the bogs. Even in mountain tracts devoted for a long succession of years to the pasturage of sheep, timber trees shoot up spontaneously wherever the land is secured from the intrusions of cattle. Many places, where the vestige of a plantation is not to be seen, retain a name of which the word "wood" forms a component part. The extension of agricultural improvement, and more especially the timber act, which gives the tenant, at the expiration of his lease, a pecuniary interest in the trees he has planted, are gradually removing this defect, the consequence of ages of disturbance and desolation.

Bog. To the same cause may be attributed in a great measure the extent of bog with which the face of the country is disfigured. The bogs are chiefly found in the elevated central district. Two lines drawn across the island, the one from Howth to Sligo, the other from Wicklow to Galway, will comprehend by much the greater portion of bog throughout the island. The total quantity, independently of small mountainous and detached patches, has been thus estimated:

Flat red bog, capable of being reclaimed	1,576,000 acres.
Mountain bog, mostly convertible into pasturage	1,255,000
	2,831,000

The bogs are distinguished, according to their substance, into red or fibrous, and black or compact. The former, which consists chiefly of the *Sphagnum palustre*, or bog-moss, is the most general. Its colour is of a reddish brown, approaching when dry to that of an olive. Its surface is generally covered with heath, which gives it a still darker hue. The black bog varies in colour from dark brown to perfect black; in which latter case it is extremely hard and close grained, separating, when broken, into angular fragments. On cutting downwards, the substance grows denser and darker, exhibiting a black mass very compact, strongly resembling pitch or coal, and when ignited emitting a smell so offensive as to prevent its general use as an article of fuel. The peat is found to rest on a blue clay, and ultimately on limestone gravel. The depth of the bogs in some places is nearly forty feet; twenty-five may be considered as a general average. In all cases they are found above the level of the sea. The greatest height of any is 488 feet, the least 25; and they invariably afford easy means of communication to some river by which their superfluous waters can be carried off, where draining is requisite for reclaiming them.

The following table exhibits the area of every county of Ireland, according to a return made to the House of Commons in 1832. It also contains an estimate of the total value of the land, the average value per acre, and a statement of the amount of county rates on an average of the years 1830–1831.

The contents in acres of the following cities and towns, each of which is a county in itself, are included in the preceding table in the total contents of the county at large, wherein they are situated. As the average value of land in the counties of cities and towns exceeds considerably that of the county at large, a statement of it is annexed, together with that of the average of the county at large, if taken without such additions:—

Statistics.

Geology. The great central plain, already described as containing by much the larger portion of the bogs, rests on a subsoil of flœtz limestone, which may be considered as in a great measure the substratum of the whole island, as there is in fact but one county, that of Wicklow, in which this rock, either of primary or secondary formation, does not appear. Secondary limestone is much more generally diffused, the primary being found only in the counties of Antrim, Tyrone, Donegal, Londonderry, Sligo, and Galway. The mountainous district in the north consists of three groups of different character. The first is that of the Mourne Mountains, of which Slieve Donard is the summit. Granite is the basis of this group, and of most of its subordinate branches. Hornblende and syenite frequently occur in the borders of the granitic region. The mountainous district in Londonderry and Tyrone, included between the Roe and Mourne, two branches of the Foyle, constitute the second northern group. Its formation is primitive. Most of the country consists of mica slate, accompanied with primitive limestone. In the eastern part is a range of secondary hills, capped by an immense covering of basalt, which spreads itself over the north-eastern part of Antrim. The third group is formed by the two chains which the valley of the Bann passes through in its course to the Atlantic. The formation is secondary, and is invariably covered with masses of stratified basalt, in some places exceeding 900 feet in thickness, but of an average depth of 545 feet, and spreading over a surface of 800 square miles.

Whin dykes. Whin dykes have been found only in the northern region. Most of them are on the coast, none more than fifteen miles from it. They are generally found in groups, several lying within a short distance of each other. They maintain a singular uniformity in their line of direction. Their bearing is constantly from south-east to north-west. Great diversity exists as to their width; that on Arrigle Mountain rises perpendicularly, like a partition wall, to the height of forty feet. Their depth has never been ascertained; but it is observed that their sides never converge, nor do they ever branch off into minute veins, or swell into what are called, in the technical language of miners, bellies.

Basalt. The same part of Ireland exhibits the only specimen of columnar basalt to be found in the island. The Giant's Causeway, in the north of Antrim, is the most remarkable specimen of it. It forms a low point, projecting into the sea, and ultimately covered with water; and consists wholly of prismatic pillars of stone, of various angular forms, all standing upright, each pillar being separated into pieces convex below and concave above, fitting into each other like a pile of dinner-plates or saucers. Along the same shore the precipices which overhang the sea present several other instances of this kind of basalt, one end of which only is visible, the remainder being buried in the mountain. At Doon Point, in the island of Rathlin, on the same coast, is another collection of columnar basalt, differing from that on the main land by having the columns curved or horizontal, as if forced from their perpendicularity by a sudden shock during the process of formation. Traces of a similar columnar formation appear in other parts of the great basaltic mass which covers most of the county of Antrim, where the rock has been accidentally denuded of its surface soil.

Another granitic region shows itself to the south of the great limestone plain in Wicklow, where it forms the base of the mass of which that county is wholly composed, whence it extends into the mountainous ridge between Carlow and Wexford. The granite field is here bounded on each side by clay slate, which constitutes the greater part of the formation of the south-east and south of the country. The total absence of metallic veins on the western side of this granitic region, whilst they exist in abundance on the eastern, forms a singular feature of the district. The southern counties are chiefly a combination of clay slate and red sandstone, the latter showing itself mostly in the mountains. In the Slievebloom Mountains, between the King's and Queen's Counties, the sandstone bursts forth in the southern part of them from out of the clay slate in which it is imbedded. To the north of these mountains three insulated hills of sandstone rise out of the limestone plain, at Moat-a-Grenogue, Ballymahon, and Slieve Gouldry. The Galtees and Kilworth Mountains, in Cork, are of sandstone. In Kerry the clay slate predominates, till it is lost in the limestone which occupies its northern parts. In the west of Connaught the division between the limestone and granitic district is distinctly marked; a line from Galway to Oughterard designates their respective limits. All to the north, spreading over part of Mayo and Roscommon, is of the former; that to the south and west is of the latter formation.

The following table exhibits a general view of the geological features of the country, arranged according to the great natural regions into which it may be divided:—

Northern Region.

Mica Slate—Donegal; Londonderry, west; Tyrone.
Flœtz Trap—Londonderry, east; Antrim, north.
Sandstone—Mayo, east; Sligo; Roscommon; Leitrim, north; Fermanagh; Tyrone; Cavan, north; Monaghan, north; Armagh, north; Antrim, south.
Clay slate—Monaghan, south; Down; Louth; Longford, north; Cavan, south; Armagh, south.
Granite—Down, south.
Coal—Antrim, north; Tyrone; Roscommon; Leitrim.

Central Region.

Flœtz Limestone—Mayo, west; Leitrim, south; Longford, south; Westmeath; Meath; Galway, east; King's; Kildare, east; Dublin, north; Clare, west; Queen's;

Statistics.

Kilkenny, north; Carlow, west; Limerick, north; Kerry, north; Cork, north.

Sandstone in the mountain ridges—Mayo; Leitrim; Clare; King's; Queen's.

Clay Slate—Clare, east.

Granite—Galway, west.

Coal—Tipperary; Queen's; Kilkenny.

Southern Region.

Sandstone in the mountain ridges—Kerry, south; Limerick, south; Cork; Waterford; Kilkenny, south.

Clay slate—Kerry, south; Cork, south; Waterford; Wexford; Wicklow, east and west; Dublin, south.

Granite—Carlow, east; Wicklow, central.

Coal—Cork; Kerry.

Coal.

By the preceding table it will be seen that coal exists in each of the provinces; that in the two southern being carbonaceous or stone-coal, the slaty glantz-coal of Werner; that in the two northern provinces bituminous or blazing coal. The most productive mines are those of Leinster, which supply the surrounding country, and are conveyed by the canal to more distant parts. The Munster collieries are considered as of the greatest extent and richness, but their coal is less in demand, from the difficulty of conveyance, owing to the badness of the roads, and the rugged nature of the country in which they are lodged. The Tyrone coal is raised in quantities barely sufficient for the demand of the immediate neighbourhood. The Antrim collieries are scarcely worked. Those of Connaught labour under the inconveniences already pointed out respecting the collieries of Munster. The quantity supplied on the whole does not exclude the importation of British coal in large quantities, which is frequently preferred for culinary and domestic purposes, even in the vicinity of the native collieries.

The following table, showing that the demand for British coal increases with the increase of the population, is a proof that the quantity of native coal raised is every year less commensurate with the wants of the population.

Account of the Quantity of Coal sent to Ireland.

Years.	Tons.	Years.	Tons.
1819	669,060	1825	695,832
1820	606,400	1826	779,584
1821	644,787	1827	650,728
1822	694,024	1828	740,071
1823	693,413	1829	840,246
1824	691,429		

The scarcity of this valuable mineral is, however, amply compensated by the almost inexhaustible supply of peat fuel raised from the bogs in every part of the country.

Mines.

Notwithstanding repeated attempts, made at considerable expense, to work the metallic mines discovered in Ireland, few have been found sufficiently productive to repay the outlay of capital employed on them. Gold was discovered accidentally in the streams flowing from the mountain of Croghan Kinselagh, in the confines of Wicklow and Wexford. Several of the peasantry having enriched themselves by collecting it, the mine was taken possession of, and wrought under the directions of the government; but, after several years experience, the result was found to be inadequate to the expenditure, and the workings have been relinquished. The principal veins of copper and lead have been found on the eastern side of the granitic region of the county of Wicklow, the western being without any. The copper mines of Cronebane and Ballymurtagh were wrought with great effect for some years. They are now less productive. A mine at Bonmahon in Waterford, and another at Allihies in Cork, are worked with much spirit; but as, from the want of a sufficient supply of native coal, the ore has to be exported to Swansea to be smelted, the profit is much diminished. Mines of copper at Cappagh, at Kenmare and Ross Island in Kerry, and at Boulard in Galway, have all been relinquished in consequence of the failure of timber for fuel. Lead mines are more numerous and more productive. The principal are at Ballycorus, and Luganure in Wicklow, Kildrum in Donegal, Clea in Armagh, Came in Wexford, Castlemaine and Kenmare in Kerry, and Sheffry in Mayo. A rich vein of iron was worked at Arigna, near Lough Allen, until stopped from the failure of fuel. On the discovery of coal in the neighbourhood, the workings were resumed with a reasonable prospect of permanent profit; but this not having been fulfilled, the workings have been again abandoned. Antimony has been found at Castleshane, in Monaghan. Gypsum, fuller's earth, manganese, and ochres of various kinds, have been raised in many parts. Amethysts, chalcedony, and garnets, have also been found. Transparent crystals are met with frequently in Kerry. Several parts of Ireland produce marble, in much demand for domestic purposes. That of Kilkenny is of a deep black, mottled with white spots, evidently the exuviæ of marine shell-fish. The marble of Armagh is red, and less susceptible of polish. Galway contains several species; but the difficulty of conveying it through a mountainous district makes them little sought for.

Fossil.

The most remarkable fossil remains are those of the Elk or Moosedeer, celebrated for the great size of the horns, one pair of which measured ten feet ten inches from tip to tip. A complete skeleton of this noble animal has not yet been found; but a fine specimen, comprising most of the bones, is preserved in the museum of Trinity College, Dublin. Mineral springs are numerous, most of them are chalybeate. Those of chief note for their medicinal qualities are Mallow in Cork, resembling the hot wells in Bristol; Ballynahinch in Down, and Golden bridge near Dublin, sulphureous and chalybeate; Swadlinbar in Cavan, and Lucan in Dublin, sulphureous; and Castleconnel near Limerick, chalybeate.

Soil.

The prevalent soil is a fertile loam, resting on a rocky substratum, chiefly of limestone. The depth, though in general not great, is in some parts such as to admit of fresh vegetable mould being repeatedly thrown up by successive ploughings to a greater depth. This occurrence is most striking in Meath, and in the district of the counties of Tipperary and Limerick, long distinguished by the name of the Golden Vale, from its extraordinary fertility. In some parts, particularly in Galway, the rock shows itself above the surface in ridges like waves, the interstices being filled with rich mould, which produces a thick, close sward, extremely grateful to sheep. Large tracts of grazing land similar to the Downs in England are unusual; the only tract of any extent of such description is the Curragh of Kildare, which has been used, time immemorial, for a sheep walk. The mountains are capable of tillage to a considerable height; and their summits, with the exception of a few of the very highest, are fit for pasturage in summer.

Climate.

The moisture of the climate, caused by the insular position of the country, and the prevalence of western and southern winds, contributes its full share to the peculiar adaptation of the soil for pasturage, insomuch so that its perennial verdure has justly acquired it the poetical title of the Emerald Isle. Neither does this peculiarity of climate, which tends so powerfully to the increase of the agricultural wealth of the country, detract from its salubrity, as is apparent from the comparative ratios of length of life in Great Britain and Ireland; the proportion of persons above an hundred years of age being in the former as ·1 to 10,000, whilst in the latter it is as ·5 to the same quantity. The same proportion applied to the several provinces of Iretistics. land, proves that the province of Connaught, confessedly the most moist in climate, is also the most favourable to the duration of human life. The ratios are as follow :—

Leinster	·5 to 10,000
Ulster	·3 to 10,000
Munster	·5 to 10,000
Connaught	·9 to 10,000

The same peculiarity of climate serves to account for the absence of venomous reptiles. Snakes are unknown, as are toads, unless, as is asserted by some zoologists, they are to be seen occasionally in parts of Kerry, where they are said to be distinguished by the name of creeping frogs. Even this latter animal is not aboriginal. Its introduction is no earlier than the last century, when, after the living animal had been imported without success, it was afterwards propagated by means of spawn.

ula-
n.

Previously to the calculations made by Sir William Petty to ascertain the numbers of the inhabitants of Ireland, scarcely any data, even for a probable or conjectural estimate, existed. The marks of the plough observable on the tops of hills which have for many years been devoted to pasture only, have been adduced as a proof that the superabundant population of former ages compelled the farmers to have recourse to the poorer ground there to raise a sufficiency of grain; but the fact has been imputed, with equal show of probability, to the disturbed state of the country, when a ferocious enemy, having desolated and possessed the more fertile lands in the plains, compelled the natives to have recourse to the poorer soils on the hills. It has also been attributed by some to the superior mildness of the climate in ancient times. The opinion of Agricola, quoted by Tacitus, that a single legion would be sufficient to conquer the island, does not indicate a very numerous population at that period; and, subsequently, the smallness of the force which enabled Henry II. to make such an impression on the country favours the same conclusion. After the close of the desolating wars of Elizabeth, in which the Irish in arms were generally exterminated as rebels, Fynes Moryson, Lord Mountjoy's secretary, asserts that not more than five or six hundred thousand escaped the edge of the sword or the horrors of famine. Sir William Petty's first estimate, as stated in the ensuing table, rests upon conjecture; his second is founded on the number of "smokes" or hearths in the country. Those given by the tax-collectors are founded on data of the same description, corrected in the case of Mr Bushe by collateral calculations. The returns of the established clergy were made at a time in which much of the country was without a resident clergy of this persuasion, and therefore must be of doubtful weight. De Burgho's, formed from information collected through the Catholic clergy, then in a state of the lowest political degradation, must be equally dubious. Newenham formed his from a great variety of ingenious calculations on the quantity of food, exports, and imports, and other similar circumstances. The first of the parliamentary inquiries was a total failure, several counties having declined to make any return, and those of several others being glaringly deficient and inaccurate. The second, Statistics. which ascertained not only the number, but the name, age, occupation, and degree of mutual relationship, of every inhabitant, particulars which still exist in the archives of Dublin Castle as a permanent record of the facts, may be considered as approximating very closely to accuracy. In the third, which might be presumed to be an improvement on the preceding in these respects, the returns of the enumerators employed were not subjected, as in the preceding instance, to any effectual check, and therefore little reliance can be placed on its statements. The returns of occupations in the city of Dublin, where their accuracy can be easily ascertained, are extremely faulty. The latest return of the population, that of 1834, rests on the same defective basis as that of 1831; but as it was afterwards checked and corrected by the commissioners of public instruction, through the medium of the resident clergy, its statements are entitled to more credit. Unhappily for statistical and political purposes, the returns of this last census have been made according to the ecclesiastical arrangement of dioceses, which it is nearly impossible to reduce to that of counties, on which all the former returns had been formed. According to these documents, it appears, that from 1672 to 1723, a period of fifty years, the population had nearly doubled. In the next fifty years, from 1723 to 1777, it had advanced more slowly; and, from 1777 to 1831, somewhat more than fifty years, it had nearly trebled, the period of doubling, from 1777 to 1805, if Newenham's calculation be correct, being but twenty-eight years.

Population of Ireland at different periods.

1652	Sir William Petty	850,000
1672	Ditto	1,320,000
1695	Captain South	1,034,102
1712	Thomas Dobbs	2,099,094
1718	Ditto	2,169,048
1723	Ditto	2,317,374
1726	Ditto	2,309,106
1731	Established Clergy	2,010,221
1754	Tax Collectors	2,372,634
1760	De Burgho, Hibern. Dominican	2,317,384
1767	Tax Collectors	2,544,276
1777	Ditto	2,690,556
1785	Ditto	2,845,932
1788	Gervais P. Bushe	4,040,000
1791	Tax Collectors	4,206,612
1792	Dr Beaufort	4,088,226
1805	Thomas Newenham	5,395,456
1811	Parliamentary Return	5,937,856
1821	Ditto	6,801,827
1831	Ditto	7,734,365
1834	Commissioners of Public Instruction	7,943,940

The following table contains the summaries of the three parliamentary returns according to counties, that of 1834 being omitted for the reason already stated.

Population by Counties.

	Order according to Surface.	Order according to Total Population.	Order according to Density of Population.	Total Population. 1813.	Total Population. 1821.	Total Population. 1831. [1] The population or extent in acres of the counties of cities and towns is not included in these calculations of ratios.

Statistics.

The returns of 1821 give a general average of five and three-fourth souls to a family. The defective state of parish registers in a country in which these documents are kept by three classes of clergymen, each observing a system of arrangement peculiar to themselves, prevents any authoritative deductions from that source as to the question of the duration of human life. But the following table, taken from the parliamentary return of 1821, on which reliance may be placed, furnishes the ratio of ages to every 10,000 of the total population at that period. The statement of ages in the late census of 1831 is still less worthy of credit than that of the numbers.

Statement of the comparative duration of Human Life, according to a ratio of Ages to every 10,000 *of the Population of* 1821.

Divisions.

The most ancient annals record a twofold division of the country by two of the descendants of Milesius, who made a line drawn from Dublin to Galway the boundary of their respective shares; of these the northern was called Leath Conn, the southern Leath Mogha. In the time of Ptolemy the island was partitioned out by a number of tribes, whose position has been determined by Whitaker as follows:—

Name according to		Modern County.	Boundary.	
Whitaker.	Ptolemy.		From	To
NORTH.				
Robogdii	Ροϐογδιοι	Londonderry, Antrim	Hornhead	Fairhead
EAST.

A subsequent division was that into the five petty kingdoms of Leinster, Ulster, Munster, Connaught, and Meath, which last consisted of the counties of Meath, Westmeath, Longford, and parts of Armagh and Louth. This division

Statistics.

existed till after the arrival of the English, when, in the reign of John, the parts subject to his sway were formed into the twelve counties of Dublin, Meath, Kildare, Uriel (now Louth), Carlow, Kilkenny, Wexford, Waterford, Cork, Kerry, Limerick, and Tipperary. No further change took place until the reign of Philip and Mary, when the King's and Queen's Counties were formed. Elizabeth divided Connaught into the seven counties of Galway, Clare, Roscommon, Mayo, Sligo, Leitrim, and Longford; and Ulster into the nine counties of which it consists at present. Wicklow was separated from Dublin, and made a distinct county, by James I. The only alteration which has occurred since, is the transfer of some of the counties of Connaught into the adjoining provinces, and the division of the county of Cork into two parts, called the East and West Ridings. This latter division took place in 1823. An act, passed in 1835, gives the lord-lieutenant a discretionary power of subdividing the larger counties, as has already been done with respect to Cork. The topographical arrangement of Ireland, given by Camden in his *Britannia*, retains the pentarchical division. It is as follows:—

Munster, including Kerry, Desmond (now incorporated into Cork and Kerry), Waterford, Limerick, Tipperary, with the county of Tipperary Holycross; *Leinster*, including Kilkenny, Caterlough (now Carlow), Queen's, King's, Kildare, Weishford, Dublin; *Meath*, including Eastmeath, Westmeath, Longford; *Connaught*, including Twomund (now Clare), Galloway, Maio, Slego, Letrim; and *Ulster*, including Louth, Cavon, Fermanagh, Monaghan, Armagh, Down, Antrim, Colrane (now Londonderry), Tir-oen, Tirconnell or Donegall.

The counties are subdivided into baronies, the baronies into parishes, and these again into townlands or ploughlands, which is the name of the smallest territorial subdivision. Besides the thirty-two counties already named, a few cities and towns, with a small surrounding portion of land, form separate jurisdictions under their own magistrates, and are also called counties. There are eight of them; five cities, Dublin, Cork, Limerick, Waterford, and Kilkenny, and three towns, Galway, Drogheda, and Carrickfergus. The territorial divisions of the country, according to the civil arrangement of it, are as follow:

Provinces.	Counties at Large.	Counties of Cities or Towns.	Baronies.	Parishes.	Parts of Parishes.
Leinster....	12	3	115	830	75
Ulster......	9	1	68	311	51
Munster....	6	3	68	708	50
Connaught	5	1	44	276	22
Total...	32	8	295	2125	198

Ecclesiastical divisions.

Established church.

The ecclesiastical arrangement of the country was, until lately, framed on the same fourfold provincial division as the civil, but under different names and with different boundaries. There were four archbishoprics, one for each province; but named from the place in which the archiepiscopal see was fixed. The number of bishoprics subject to each of these varied at different periods, and two or more sees were frequently united to afford a revenue competent to maintain the dignity of the holder. Formerly the dioceses were much more numerous than at present, as may be seen from the following list, taken from an old Roman Provincial, and given nearly in the words of the original.

Armagh, containing Meath or Elnamirand, Down or Dundalethglass, Clogher or Lugundun, Connor, Ardachad (Ardagh), Rathbot (Raphoe), Rathlue (now part of Derry), Daln-liquir (unknown, but by some supposed to have merged into Meath), Dearri (Derry); *Dublin*, containing Glendelagh, Fern, Ossori or De-Canic, Lechlin, Kildare or Dare; *Cassel*, containing Isle of Gatha (now Innis-Scattery, and united to Limerick), Limric, Laon or De Kendalnan (now Killaloe), Cellumabrath (called also Fenebore, now Kilfenora), Melie or Emileth (Emly), Ross or Roscrea, Waterford or Baltifordian, Lismore, Clone or Cluanan (Cloyne), Cork, Rosalither (now part of Cork), Ardforth; *Tuam*, containing Duac or Kilmacduach, Mage (or Mayo, now part of Tuam), Enachdun (also part of Tuam), Cellaiar (unknown), Roscommon (translated to Elphin), Clonfert, Achad (Achonry), Lade or Killaleth (Killala), Conani (Clonmacnois, now part of Meath), Kilmunduach (Kilmacduagh), Elphin.

The modern division, until the alterations made since the reform act, is as follows:—

List of the archbishops and bishops of Ireland, according to the ecclesiastical provinces as they were arranged previously to the act for the reduction of ten bishoprics, with the amount of their respective incomes. Those marked with an asterisk are the bishoprics to be reduced under the act. Those in Italics are already united each with another see, according to its provisions.

ARMAGH	L.17,669	16	7
Meath and Clonmacnois	5,220	10	6
* Clogher	10,371	0	2
Down and Connor	5,896	0	1
Derry	14,193	3	9½
* *Raphoe*	5,787	8	2
Kilmore	7,477	17	0½
* Dromore	4,813	6	9
DUBLIN and Glandclagh	9,320	12	9
* Kildare and Christ-Church Deanry	6,451	13	3

TUAM and Ardagh	8,206	3	9¾
* Elphin	7,034	8	9
* *Clonfert* and *Kilmacduagh*	3,260	19	4¾
* *Killala* and *Achonry*	4,081	18	8
Total	L.151,127	12	4¼

By the new ecclesiastical arrangement there are to be but two archbishoprics, Armagh and Dublin, the two others being reduced to the rank of bishoprics. The bishoprics are also to be consolidated under twelve bishops, instead of eighteen, as heretofore. The arrangement, when completed by the falling in of the several sees on the demise of their present incumbents, will stand as follows:—

Archbishops and Bishops since the Reduction, with their respective Incomes.

ARMAGH, with Clogher	L.13,170
Meath	5,221
Derry, with Raphoe	8,033
Down, with Connor and Dromore	5,896
Kilmore, with Ardagh and Elphin	7,478
Tuam, with Killala and Achonry	5,020
DUBLIN, with Glandclagh and Kildare	9,321
Ossory, with Leighlin and Ferns	6,550
Cashel, with Emly, Waterford, and Lismore	7,354
Cloyne, with Cork and Ross	5,009
Killaloe, with Kilfenora, Clonfert, and Kilmacduagh	4,532
Limerick, with Ardfert and Aghadoe	5,369
	L.82,953

Statistics.

The other dignitaries of the establishment are thirty-three deans, twenty-six precentors, twenty-two chancellors, twenty-one treasurers, thirty-four archdeacons, two provosts, and one sacristan, besides which there are 178 prebendaries and nine canons. Of these, forty-two of the dignitaries and fifty-two prebendaries are sinecurists, or nearly so, requiring only an occasional attendance at the cathedral church; the remainder derive their incomes from benefices with cure of souls, and may therefore be considered as parochial clergy. There are likewise some subordinate corporations, consisting of five canons, fifty-nine vicars-choral, and fifteen choiristers, in twelve of the cathedral churches. The number and names of parishes, according to the ecclesiastical arrangement by which the clerical duties are performed and the tithes collected, vary considerably from the civil arrangement according to which the county assessments are levied. The latest returns state the number of parishes at 2348, which are condensed into 1385 benefices, each under a separate incumbent, who enjoys the emoluments, as follows:—

Statement of the Number of Parishes and Benefices.

Provinces.	BENEFICES, CONSISTING OF			TOTAL OF	
	A Single Parish, or Part of One.	Two or more Contiguous.	Parishes or Parts not Contiguous	Benefices.	Parishes.
Armagh	396	90	16	502	658
Dublin	174	115	22	311	624
Cashel	301	132	36	469	791
Tuam	36	54	13	103	275
Ireland	907	391	87	1385	2348

The income by which the whole establishment is maintained, is as follows:—

Archbishops and bishops	L.151,128
Deans and chapters	1,043
Economy estates of cathedrals	11,056
Subordinate ecclesiastical corporations	10,526
Dignities and prebends without cure of souls, and exclusive of those held by bishops	34,482
Glebe lands	92,000
Tithes	555,000
Minister's money	10,300
	L.865,535

The population for whose spiritual benefit this extensive and complicated structure of ecclesiastical jurisdictions is maintained, is thus distributed among the several sects, according to the late returns of the commissioners of public instruction, as shown by the following table, which exhibits also the proportion per cent. borne by the several religious denominations to the total population:—

Denomination.	Total Population.	Proportion per cent.
Established church	852,064	10·726
Roman Catholics	6,427,712	80·913
Presbyterians	642,356	8·086
Other dissenters	21,808	0·275
Total population	7,943,940	100·000

By referring to the amount already stated as being the income of the established church, it will appear, that whilst the Roman Catholics provide for the total maintenance of their clergy by voluntary contribution from amongst themselves, the religious instruction of the Protestant portion of the population costs the country two shillings per head annually; or, in other words, every family has to contribute nearly twelve shillings a year towards the maintenance of the established clergy; whereas, if that body were to derive its support solely from the contributions of its own members, as is the case with the Roman Catholic clergy, the sum to be annually paid by every Protestant, man, woman, and child, in order to make up the sum of L.865,000 deemed necessary for the maintenance of their establishment, would be one pound each, or six pounds for every family.

Roman Catholic church.

The hierarchy of the Roman Catholic church still continues of the same form that it bore previously to the Reformation, consisting of four archbishops and twenty-two bishops, to which another has been lately added; the town and vicinity of Galway, which had been hitherto an exempt jurisdiction under an ecclesiastical head styled warden, having been erected into a see. The hierarchy is supported by the profits of some one or more parishes in the respective dioceses, by fees from the incumbents of the others, and by those of marriage licenses. The incomes of the bishops, as well as those of every class of Catholic clergy, are derived wholly from voluntary contributions. Monasteries and convents are numerous, and some, particularly those for females, are well endowed.

Presbyterian church.

The presbyterian church, which flourishes chiefly in the north of Ireland, is governed by a synod, which chooses a moderator annually as its president. The ministers are maintained partly by the voluntary contributions of their respective congregations, and partly by an annual parliamentary grant called the Regium Donum.

Representation.

Ireland is represented in the imperial legislature by twenty-eight temporal and four spiritual peers, and 105 commoners. The temporal peers hold their seats for life; the spiritual peers sit annually, according to a rotation of sees. The changes in the right of franchise for the election of commoners have been very considerable since the passing of the Catholic relief bill, which diminished the number of electors in an extraordinary degree. The following table shows the alterations caused by the legislative measures adopted since the passing of that act, as compared with the previous state of the constituency. The first line gives the average number of electors before 1829. The other lines show the effects since produced by subsequent acts of parliament.

Constituency.

Year.	L.100.	L.50.	L.20.	L.10.	40s.	Total.
1829,	303	18,066	6806	...	191,606	216,791
1830,	98	17,409	7319	11,804	...	39,772
1832,	31	10,214	8414	42,066	...	60,725

Government.

The executive government is committed to a lord-lieutenant deputed by the crown. He holds his place during pleasure, but is generally continued in office for five years. He is assisted by the privy council, a body also nominated by the king, and invested with extensive powers, as well judicial as ministerial; also by a chief secretary, who is a member of the House of Commons, and is the person looked to by the legislature for the management of the country. Each county is also placed under a lord-lieutenant nominated by the crown, who is considered to be responsible for the preservation of good order, and has much weight in the nomination of the magistrates. He is aided by a number of deputy lieutenants, also nominated by the crown.

The levy and expenditure of money for local purposes is in the hands of the grand juries in every county; the members are named annually by the high sheriff, from among the chief landed proprietors or their agents. This arrangement has given rise to much abuse in the management of the funds intrusted to them. The sums levied bear very heavily on the industry of the actual landholder; and the application of them is subject to strong imputations, often too well founded, of fraud and favouritism.

Law.

The administration of law is vested in the lord chancellor, who is assisted by the master of the rolls, and in the twelve judges of the supreme courts, namely, the King's Bench, Common Pleas, and Exchequer. The judges visit the counties twice a year, in six circuits, for the decision of weightier causes, and the investigation of heavy offences. Minor cases are brought before the magistrates at petty sessions, who are then assisted by a lawyer nominated by the crown, under the name of assistant barrister.

Military.

A very numerous armed force has long been maintained in Ireland. Regular troops, to the number of from twenty to twenty-five thousand men, are quartered in barracks in all parts; besides which, a well-armed and organized body of police, amounting to nearly 6000 effective men, is maintained. These are placed under the immediate control of stipendiary or salaried magistrates, appointed by the crown. In addition to the military and police, a force of armed yeomanry, mostly Protestant, was supported until lately, and called out occasionally into active service.

Revenue.

Before the arrival of the English, the revenues of Ireland were paid in cattle; and even after that period the custom prevailed for several centuries in the parts less subject to foreign influence. Traces of it have been met with so late as the reign of Elizabeth. The new government, under the English, introduced the method of raising money by subsidies. John exacted a subsidy from the Irish clergy, and established the court of exchequer for the general management of the revenue. The same method was continued during the reigns of Henry III. and the first Edwards; but the income thus extracted from the people proved so inadequate to meet the wasteful expenditure caused by a repetition of foreign wars and intestine commotions, that recourse was had to the legalized extortion of coygne and livery, which was the levying of man's meat and horse's meat for the soldiery in time of service. The amount of the regular revenue, in the reign of Edward III., is stated by Walsingham and Holingshead to have been L.30,000; but Sir John Davis, who collected his information from the pipe-rolls, and other authentic sources, reduces it to L.10,000. The most remarkable financial measure of Richard II. was a tax upon absentees. In 1433, the eleventh of Henry VI., the revenue was reduced to L.2339. 18s. 6d., whilst the expenses of the government were L.2348. 16s. 11½d., thus exceeding the income by L.18. 17s. 5½d. At the latter end of the same reign, the Duke of York, when sent over as lord-lieutenant with extraordinary powers, not only obtained the whole revenue, but stipulated for an additional supply from England of 4000 marks for the first year, and L.2000 for every year thereafter. Edward IV. raised money by the imposition of duties on all merchandise sold in Ireland except hides. In the fifteenth year of Henry VII. a duty of one shilling in the pound was laid on all merchandise imported and exported, except wine and oil; and a tax, by way of subsidy, of 13s. 4d. on every hide of land. During this reign the revenue seldom exceeded L.5000. During the reign of Henry VIII. the revenue was increased by the suppression of monasteries. The laws against absentees were also enforced. During the first fifteen years of Elizabeth, the revenue was L.120,000, or L.8000 per annum, according to Ware, though Sinclair states it at only L.6000, whilst the expenses amounted to L.490,779. 7s. 6½d. In 1599, at the close of Tyrone's rebellion, L.600,000 were spent in six months; and Sir Robert Cecil affirmed that Ireland had cost the queen L.3,400,000 in ten years' time. The pacific reign of James tended much to the improvement of the revenue. The customs increased from L.50 to L.3000, and at the close of his reign to L.9700. The wardships and other feudal rights produced about L.10,000, notwithstanding which the income was inadequate to the expenditure. To defray the expense of the army, an order of baronets was established, by which L.98,500 was raised, in addition to which L.247,433 were remitted from England to clear off the debts incurred by Elizabeth. The Irish parliament granted the same king a subsidy of 2s. 8d. in the pound on every personal estate of three pounds annual value, and fourpence in the pound on every real estate of one pound value; an act of liberality with which James was so much pleased, that he declared "he would hereafter hold his Irish subjects in equal favour with those of his other kingdoms." In the succeeding reign Strafford raised the customs to four times their previous amount. In the same reign the first mention is made of an excise tax. The distractions of the country till the restoration afforded little means to ascertain the progress of the revenue. Thurloe, however, in his state papers, mentions that the revenue for two years ending in 1657 amounted to L.137,558. 13s. 3d., whilst the expenditure was L.142,509. 11s., leaving a deficit of L.4959. 17s. 9d. When the Irish parliament met after the restoration, it granted, first, an hereditary revenue to the king, his heirs and successors; second, an excise for maintaining the army; third, the subsidy of tonnage and poundage for the navy; and, fourth, a tax of two shillings each on hearths, in lieu of the feudal burdens, which were then abolished. After the revolution, the information respecting this important element of national statistics becomes more precise and satisfactory. The revenue, from the landing of Schomberg in 1689 till the end of the reign of William, was as follows, the total of the previous military expenditure of the war with James having amounted to L.3,851,655:

1689	L.8,834	1696	L.513,534
1690	93,910	1697	548,967
1691	274,949	1698	601,846
1692	393,926	1699	701,932
1693	444,183	1700	766,620
1694	430,534	1701	697,955
1695	438,304	1702	581,286

During the earlier part of Anne's reign the income exceeded half a million, but in her latter days it was less productive. In the reign of George I. the state of the revenue continued nearly as in the preceding reign. In that of George II. there was a surplus, which was applied, not always judiciously, to public works.

From the earlier part of the reign of George III. to the present period, the total amount of the public income was formed of the customs, excise, land tax, assessed taxes, stamps, postage, duties on pensions and offices, lotteries, and poundage pells and casualties. Up to 1811 the first four of these make but a single item in the parliamentary account. After that date the customs are specified as a separate item. The Irish lottery ceased at the union; the land tax at the consolidation of the exchequers in 1817;

istics. the assessed taxes were repealed in 1822–23, since which time the whole income is formed of the items of customs, excise, stamps, postage, and poundage and casualties. The following table, exhibiting the receipts for every fifth year, from 1790 to 1830, will give a general view of the progress of taxation in its leading departments during that period. Statistics.

Account of the Receipt of the Revenues of Ireland for every Fifth Year from the 5th of January 1790, *to the 5th of January* 1830, *arranged under the several Heads of Collection.*

The expenditure for every fifth year corresponding with the years in the preceding table is given in that which follows. The first item states the payments of interest and management of the public funded debt; the second, the payments out of the consolidated fund, which include the civil list, miscellaneous payments, and interest on Irish treasury bills; and then follow the charges for the army, the navy, and the miscellaneous expenditure. The last column consists chiefly of advances for the relief of trade, and other public objects.

Table of the Public Expenditure for every Fifth Year from 1790 *to* 1830.

The national debt of Ireland, incurred by an excess of expenditure beyond the income of the country, increased with great rapidity towards the close of the last century and till the year 1817, when it ceased to form a separate item in the public accounts, in consequence of the consolidation of the British and Irish exchequers. Its progressive increase since the revolution is exhibited in the following table.

Public Debt of Ireland.

1716	L.16,106	1770	L.628,883
1720	87,511	1780	1,067,565

1762	223,438	1817	134,602,769

urces of venue. Ireland has, till of late years, been almost exclusively a pastoral country. The population drew its chief sustenance from cattle, and the few manufactures were derived from the same source.

oollens. The rich pasturages, adapted both for black cattle and sheep, furnished in abundance the material for two branches; the woollen trade, and the tanning of leather. The former was carried on to a considerable extent at a very remote period. Traces of an export of woollens to Italy as early as the reign of Edward III. have been discovered. The manufacture was an object of legislative interference as early as the third year of Edward IV. (1462); and an act of Henry VIII. in 1542 expressly notices the exportation of woollen yarn from Ireland. The former of these acts was the first attempt to restrict the importation of foreign goods into England, to the prejudice of the native artist. By it woollens, laces, and ribbons were prohibited; but a provision was inserted, "that all wares and chaffers made in the land of Ireland may be brought and sold in this land of England, as they were wont to do before the making of this statute." Although subsequent prohibitory acts of Elizabeth, James, and Charles I. make no mention of Ireland, there is little reason to suppose that any change was made as to the freedom of trade with this country, until the 12th of Charles II., when an act was passed in the English parliament, imposing such rates of duty as effectually prevented importation. By an act of the same year, the exportation of wool from England was prohibited generally, as was that from Ireland, to foreign countries. An act of the 9th and 10th of William III. prohibited the exportation of fullers' earth to Ireland. But the great blow to this branch of national industry was caused by an address from both houses of the English parliament to William in 1698, praying him, "with a view to secure the

Statistics.

woollen manufacture as much as possible entire to England, that he would use his utmost diligence to hinder the exportation of wool from Ireland, except to be imported hither; and for discouraging the woollen and encouraging the linen manufactures of Ireland." The immediate consequence of these addresses was the passing of an act prohibiting the exportation of wool or woollens, except to England, from which country the manufactured article was already excluded by the act of the 12th Charles II., still in force. Under this code England effectually restrained the Irish trade. The supply of the raw material was narrowed by the impossibility of importing British wool, and the manufactured goods were confined to the domestic consumption of the country. Scarcely a vestige of this ill-advised system now exists. The laws which prohibited the exportation of Irish woollens to foreign countries, and to the British colonies, were repealed in 1779. By the act of union, the duties on woollens imported into either island were confined to those called "old and new draperies;" and the high duties of Charles II. were reduced to eightpence halfpenny per yard on the old, and twopence three farthings on the new draperies. By the same act, England relaxed her monopoly so far as to permit the export of wool and woollen yarn duty free to Ireland. According to evidence before the House of Commons in 1832, one third of the cloth used in Ireland is brought from Great Britain; but as that imported is usually of finer quality, the value of it is estimated at one half. The manufacture of Ireland is confined to the coarsest description of goods; every attempt to introduce the manufacture of the higher-priced articles has been the cause of the ruin of the speculator who ventured upon it. Broad cloths and blanket manufactories exist nowhere north of Dublin; flannels are made in Wicklow, and blankets in Kilkenny. Frize of the coarsest kind is made in most counties by the farmers, during the intervals of their agricultural labours, for their own use, and for the supply of the adjoining districts.

The following tables show the quantity, quality, and declared value of woollens imported since the union. The imports previous to that period will be found in a general table of imports and exports under a subsequent head.

Statistics.

The same legislative measure which deprived Ireland of its woollen manufacture stated, that "if the Irish turned their industry and skill to the settling and improving of the linen manufacture, they should receive all the countenance, favour, and protection for its encouragement, and promotion to all the advantage and profit they might be capable of deriving from it." This declaration should not lead to the inference that the manufacture had been previously unknown or disregarded in Ireland. On the contrary, the use of linen was so prevalent amongst the higher orders, that sumptuary laws were enacted to check its excessive use. The unfortunate Earl of Strafford seems also to have anticipated the views of the British manufacturers on the subject. He, however, took a more honest, and perhaps a more judicious course. Instead of extinguishing the woollen trade by exclusive duties, he laboured to foster that of linen. He imported flax seed in large quantities from Holland, and held out premiums to induce Flemings and Dutchmen acquainted with the manufacture to settle here. On these laudable objects he spent upwards of L.30,000 of his private fortune; and his example was followed by the Duke of Ormond. Still, however, the woollen trade prevailed, particularly in the south and west, where the climate and the extensive pasturage for sheep insured a copious and cheap supply of the raw material. In the same spirit, an act was passed by the English parliament in 1696, to encourage foreign linen manufacturers to settle in Ireland; and with that view all articles made of flax or hemp in this country were admitted into England duty free, a privilege which is estimated to have given that branch of trade an advantage of L.25 per cent. over other nations in the English market. The Irish parliament, responding to the sentiments and wishes of that of England, promised that "it would heartily endeavour to establish the linen and hempen manufacture, so as to render it useful to both kingdoms;" adding, that "it hoped to find such a temperament in respect to the woollen trade here, that the same may not be injurious to England." The "temperament" here announced was evinced most effectually by laying prohibitory duties on the export of its own woollens, thus accepting the compact on the part of Ireland, and giving the country an incontrovertible claim upon England for a perpetual encouragement of that branch which was to be nurtured in lieu of the natural staple of the country. In furtherance of the measures mutually agreed on between both kingdoms, a board of trustees for the encouragement of the linen manufacture was established in 1710, consisting of a number of individuals of most influence in each province. Under its control a code of regulations was devised and maintained, which extended to the most minute particulars of the processes, and had the effect for many years of securing the fabric a decided preference both in the home and foreign market. A large sum was annually granted to this board, for premiums and the supply of wheels and other implements, which was continued till the year 1830, when the grants were discontinued, and the board consequently ceased to act. The flax seed is chiefly imported. Little is grown in the country, as, notwithstanding all the exertions made by the grower, the plant raised from it is considered as of inferior quality. The principal part of the seed is brought from America, the remainder from Holland, Prussia, and Great Britain. The following table shows the number of hogsheads and of acres sown during a period of four years.

	Hogsheads.	Acres.		Hogsheads.	Acres.
1818	47,607	80,785	1820	52,416	77,755
1819	44,431	91,728	1821	45,163	83,312

The three following tables show the value of the brown or unbleached linen sold in the several linen markets in Ireland during a period of four years; also the state of the export of linens both plain and coloured, and of linen yarn, in periods of ten years each since the formation of the linen board in 1710; exhibiting both the total amount of quantity and value during each period, and the average annual amount of quantity and value for each year in the respective periods. The sums stated in the former of these tables are the first cost paid to the manufacturer by the country purchaser; the value of most of the linen sold is afterwards considerably increased by the process of bleaching and other treatment.

Cotton. The cotton manufacture was early an object of attention to the Irish parliament, which endeavoured to secure a monopoly of the home market by high import duties and by bounties. The first cotton mills were erected at Prosperous, in the county of Kildare, and in Belfast, about the year 1784. From that period till the union, it throve, in consequence of the measures adopted to prevent foreign competition. At the union it was arranged that the then existing duties should continue for eight years, after which they were to be gradually lowered, by eight annual reductions, in such manner that, after the year 1816, they should stand at ten per cent. *ad valorem*. The progress of the manufacture has been very slow as compared with that of Great Britain. The alteration of the scale of duties materially affected the home demand, and the immense capital and great superiority of the British artist have contributed much to secure to his manufacture a preference in the foreign market; yet it is a curious fact, that cottons printed in Dublin are sent to Manchester, where they are purchased by the Irish retailer, and obtain a preference by the home consumer. The following table of the quantity of cotton wool and yarn imported from all quarters affords a general view of the increase of the manufacture from its origin to 1823.

Account of the quantities of Cotton Wool and Yarn imported in 1771, and for every Fourth Year after, to 1823 inclusive.

Silk. The silk manufacture was introduced into Ireland by French emigrants after the revocation of the edict of Nantes. Its principal seat was the city of Dublin, where it was maintained by the aid of protecting duties. Some feeble attempts to fix it in the country parts failed completely. The last of these was so lately as 1825, when a company was formed for the purpose of fixing the trade on a secure basis in the south of Ireland, by rearing the silk-worm there, and thus having the benefit of the raw material for the labour of producing it; but after considerable expense had been incurred for the purchase of ground and the planting of mulberry trees, the scheme was relinquished as hopeless. One branch of the manufacture, a fabric of mixed worsted and silk, known here by the name of tabbinet, and in England by that of Irish poplin, is in considerable demand, both at home and elsewhere, for the richness and beauty of the texture. It is almost the only branch now flourishing. The general trade has been nearly annihilated by the removal of the protecting duties since the union. The following table of the official value of the silk imported since the commencement of the manufacture evidently proves its decline.

Statistics.

Statement of the Value of Silk imported into Ireland, in Irish currency, for 1771, *and for every year afterwards to* 1823 *inclusive.*

1771	L.80,361	1799	L.63,626
1775	95,224	1803	74,423
1779	57,116	1807	53,225

1791	81,413	1819	65,372
1795	51,930	1823	45,523

The manufactures of iron, copper, and brass are very confined. The few iron founderies that still exist are limited to the execution of orders for works or manufactories carried on in the neighbourhood, which necessarily require the article to be made according to pattern, and on the spot. The same observation applies to those of copper, brass, and lead. The great advantage enjoyed by Great Britain in the inexhaustible stores of native metal, particularly iron, and of coal, together with the command of capital, and the elegance and cheapness of finish, arising from long experience, deprives Ireland of any reasonable hope of a successful competition in these branches, even for the wants of its own population.

The manufacture of glass was carried on to a considerable extent. There were four establishments in Dublin, two in Belfast, two in Cork, one in Waterford, and one in Derry. The raw material, except coal, was to be had in abundance, and in some places of excellent quality. The white glass was in much estimation for its goodness and brilliancy. The bottle manufacture supplied the entire demand of the country. But the trade has sunk under the effects of the assimilation of the duties with those in Britain. There is now scarcely an establishment existing.

Provision trade.

The making up of provisions for the army and navy, and for the foreign market, has long been a great source of wealth to the country. The principal part of the provision trade was carried on in Cork until of late years, when Belfast and Newry obtained a large share of it. The flesh is suffered to lie seven or eight days in salt before it is packed. The expedition with which the whole process is then carried on is astonishing. The beef, when cured, is assorted according to quality, in three classes, called planters', India, and common beef. The hides are returned to the grazier: those of the oldest cattle are most valued. The fat is disposed of to the tallow merchant. Bacon and hams are salted on an extensive scale for London, at Limerick, Clonmel, Waterford, and Belfast, in which last town the superior mode of preparing the article has given it a high character. The progress of the trade may be judged of by the following tables, exhibiting a statement of the quantities of salted meat and butter exported every fourth year from the union until 1825, when the official returns cease to give separate details for Ireland; and of the quantity of salt imported every tenth year, from the earliest returns to the same period.

Quantities of Beef, Pork, Bacon, Hams, Butter, and Lard, exported in every fourth year since the Union.

The use of spirituous liquors was known in Ireland at an early period. Camden, who derived his knowledge of the country from writers that lived long before himself, states that "the excessive moisture of the air and soil occasions many to be troubled with fluxes and catarrhs, particularly strangers, to stop which they have excellent usquebagh, much less heating and more drying than ours." But the article itself was not subjected to fiscal regulations till the reign of Charles II. when, in 1661, an excise duty of 4d. per gallon was laid on it, and continued at that rate till 1715, when an additional duty of 3d. was imposed; and two years after a further duty of 1d. This duty in 1719 produced a revenue of L.5785. In 1785 the duty was fixed at 1s. 2d., and so continued for some years. Its produce at that rate in 1791 was L.204,648. After a variety of changes, by which it was progressively raised, it stood in 1814 at 5s. 6d.; and though, for a year or two after, an attempt was made to augment it to 6s. the experiment was found to be so unsuccessful that it was lowered to the former rate after two years' trial. Severe restrictions were imposed, and a most complicated and harassing system of checks established, upon every part of the process, to prevent the possibility of yielding to the temptations to defraud the revenue occasioned by the enormous charge of duty. The consequence was, that the whole spirit trade was thrown into the hands of a few capitalists, who, by their mutual understanding, were enabled in their turn to check and control the officers of the revenue in their attempts to stop the issue of spirits from the distilleries which had not paid duty; whilst in the country parts, and particularly in the mountainous districts in the north and west, illicit distillation was carried to an extent that ultimately set all means to prevent it at defiance. No country has suffered more than Ireland from the excessive height to which the duties on home-made spirits have been carried. If heavy taxes, enforced by severe fiscal regulations, could make a people sober and industrious, the Irish would be the most so of any on the face of the earth. In

Statistics.

order to make the possessors of property join heartily in suppressing illicit distillation, the novel expedient was resorted to of imposing heavy fines on every parish or townland in which an illicit still was found at work, and those detected in making it were transported for seven years. But instead of the effect looked for, these unheard-of severities not only did not check the practice, but filled the country with bloodshed, and established an organized resistance to the laws. In 1811, when the duty was 2s. 6d. per gallon, 6,500,000 gallons were paid for; in 1822, when it was raised to 5s. 6d., only 2,950,000 gallons were brought to charge, whilst at this latter period the commissioners of revenue, from whose reports this statement is extracted, estimate the total consumption at not less than 10,000,000 gallons, of which therefore upwards of 7,000,000 paid no duty. The profits on the manufacture were such as to induce the country people to run all risks, and to set at defiance every effort of the constituted authorities to put down the practice. Another mode was then at last resorted to. The duties were reduced in 1822 from 5s. 6d. to 2s. the wine gallon, or 2s. 4d. the imperial gallon. The results are best exhibited by the following table, showing the quantity of spirits that paid duty each year, the rate of duty, and the net amount of revenue collected.

Years.	Gallons Imperial Measure.	Rate per Gallon.	Net Amount of Revenue.
1821	2,649,179	5s. 6d. per Irish gal...	L.912,288
1822	2,328,387	Ditto....................	797,518
1823	3,348,505	Ditto....................	634,460
1824	6,690,315	2s. per English gallon	771,690

1826	6,837,408	2s. 10d. per imp. gal...	964,509
1827	8,260,919	Ditto....................	1,122,096
1828	9,937,903	Ditto....................	1,395,721
1829	9,212,223	Ditto....................	1,305,064
1830	9,004,539	2s. 10d., 3s., and 3s. 4d. per do.	1,409,128
1831	8,710,672	3s. 4d..................	1,451,580
1832	8,657,756	Ditto....................	1,442,845
1833	8,168,596	Ditto....................	1,360,769
1834	9,763,808	3s. 4d. and 2s. 4d.....	1,464,581

A superficial view of this table might lead to the conclusion that the consumption of spirits in Ireland had nearly trebled since 1823; but, in fact, the apparent increase was caused solely by the general use of licensed instead of illicit spirits under the reduced scale of duties. The measure was most effective, and it will be found by the succeeding table, exhibiting the progress of convictions under the illicit distillation laws, that the subsequent increase of duty in 1830 has been pernicious. The truth is, that 2s. 4d. was as high a duty as the article would bear, and the additional 6d. has again thrown the balance in favour of the smuggler, and led to a partial revival of illicit distillation. The subsequent reduction of the duty in 1834 proves that this financial error has been perceived and corrected.

Convictions for Illicit Distillations. (Inspectors of Prisons for 1829 *and* 1835.)

1822	1003	1829	617
1823	1057	1830	658
1824	912	1831	276
1825	994	1832	363
1826	824	1833	896
1827	693	1834	1149
1828	652		

From the preceding statements it is evident, that as long as the undue proportion between the duty and the intrinsic value of spirits induces a continuance of the practice of illicit distillation, no official returns can afford adequate data for calculating the quantity of home-made spirits consumed in the country. As far, however, as a conclusion can be drawn from the number of houses licensed for the retailing of spirituous liquors, it would appear that Ireland is not excessive in this point. The number of spirit licenses granted in 1834, in each part of the united kingdom, were, for

	New.	Renewed at an increased rate of duty.	Total.

Total......	2025	79,981	82,006

Breweries.

There are breweries in most of the large towns in Ireland, not only adequate to the internal demand, but allowing an export, which has been increasing for the last few years. The importation of beer from Great Britain has been progressively diminishing for many years, particularly since the union, as will appear from the following table of the average amounts of the quantities of beer and ale imported in the several periods stated.

From 1721 to 1760....... 6,307, average during 40 years.
1760 to 1800.......56,323, average during 40 years.
1800 to 1810....... 3,710, average during 10 years.
1810 to 1821....... 512, average during 10 years.

It does not, however, appear that the consumption of home-brewed beer has increased in proportion to the diminution of that imported. The number of barrels of malt used in the breweries of Ireland in 1810 was 446,436; in 1822 it was only 361,301; and, according to another official account, the number of quarters of malt used by brewers in 1823 was 174,466, whilst in 1833 it was 192,867, an increase not at all proportional to the increase of the population during the same period.

The exports of ale and beer from Ireland, as compared with those from England and Scotland, show that the article produced here is increasing steadily in demand in foreign countries.

	England.	Scotland.	Ireland.

1830	74,902	3,131	15,207

Agriculture.

Ireland, as has been already noticed, is, both from soil and climate, a pastoral country. The habits of the people tended to keep it such. Nor was it till the beginning of the last century that any efforts were made to introduce an attention to tillage upon an extended scale. Primate Boulter, when one of the lords-justices, pressed strongly on the British government the importance, or rather the necessity, of enforcing a tillage system; and for this purpose proposed a law in 1727, to compel landholders to till five acres out of every hundred in their possession, exclusive of meadows and bogs; and also to release tenants to the same extent from the penal covenants against tillage, inserted with equal want of policy and justice into their

Statistics.

leases. Mr Dobbs, who wrote several valuable tracts on Ireland about the same period, ascribes the poverty of the country to the neglect of tillage. The Irish legislature at length became sensible of the necessity of some general and vigorous expedient to direct domestic industry into this channel. It saw a large sum annually remitted to England to purchase grain, producing a drain of capital, and holding out as it were a premium to indolence at home. The remedy devised was not the best, but it produced to a certain degree the effect. Bounties were given for corn brought by land-carriage to Dublin, where the demand for grain was greatest. The progress of the excitement thus produced appears by the progressive increase of the amount of bounties, which were ultimately withdrawn, partly because the desired object, the direction of public attention to this branch of national industry, had been attained, but more so in consequence of the many frauds and abuses which had crept into its management.

The amount of the bounties paid was, in

1764	L.5,483
1767	6,074
1770	18,706
1774	49,674
1777	61,786
1780	77,800

The counties which drew the largest amount of bounty were Tipperary, Kilkenny, Meath, Queen's, and Carlow.

The nature of the tenures by which land was held had also an unfavourable influence on the agricultural improvement of the country. After the transfer of by much the greater part of the territorial surface to Cromwell's adventurers, the original patentees in many instances were glad to grant leases at long terms of years, and in many cases in perpetuity, for what would now be considered as trifling considerations. These lands, as their value increased by the increased feeling of the permanency of the new government after the revolution, were re-let by the holders, who preferred to draw a fixed rent from them, rather than to hold them in their own hands. Hence arose the class of middlemen, sometimes in a triple or quadruple order, living in independence and idleness on the labours of the occupying tenant, the whole of whose earnings, beyond the means of a bare subsistence for his family, was drawn away from him by this succession of intermediate landlords.

The system of exaction thus produced was increased by the operation of the penal law, which forbade a Roman Catholic to hold any land if the rent did not amount to two thirds of the actual value, thus leaving one third only for the subsistence of the tenant and the payment of tithes and local taxes. Land was essential for the existence of the Catholic peasant, who could not afford to emigrate. He therefore paid the rack rent, and of course had the preference as a tenant; and the Protestant was forced to follow the example or quit the country.

The size of farms, as well as their mode of culture, varies greatly in different parts. Generally speaking, in the manufacturing districts of the north, the small allotments of land, there dignified by the name of farms, are limited to a few acres, the cultivators of which no more deserve the name of farmers than would the occupiers of mere cabbage gardens. In the grazing counties the farms are of very great extent, often spreading over upwards of a thousand acres; whilst in the counties in which greater attention is paid to tillage, they are more moderate in dimensions. The mixture of grazing and tillage so frequent in England is much less usual here, except on the farms of gentlemen, where both the feeding of stock and the growth of grain are carried on, in numerous instances, to as high a state of excellence as in any part of Great Britain. Nor are there any large tracts of country exclusively devoted to the breeding of cattle, as in the highlands of Scotland.

Grazing.

The grazing of various kinds of stock is seldom combined. A usual mode, with respect to black cattle, particularly in Connaught, is to collect yearling calves, which are fed till they are four years old, when they are sold, at the great annual fair at Ballinasloe, to the graziers of Limerick, Tipperary, Roscommon, and Meath, by whom, when fattened for the butcher, they are either shipped alive for Liverpool, or sent to the markets of Dublin and the larger northern towns, or to Limerick and Cork, where they are cured for exportation.

The dairy farms form a conspicuous feature in the rural economy of the country, occupying a still larger portion of the soil than that used by the grazier. Butter, much celebrated for its excellence, is exported in large quantities. That of Carlow bears the highest character in the foreign market. It may appear strange that a country whose character stands so high in the production of butter, should be so unsuccessful in that of cheese. Yet such is the fact. With the exception of some made in the county of Antrim, particularly at Carrickfergus, Irish cheese is of very inferior quality. The failure of the many attempts to produce a good article may in most cases be attributable to the want of that tact in the management of it during its fabrication, which is only to be acquired by long and persevering practice. Yet it is stated of Lord Hawarden, whose estate lies in one of the richest tracts in Tipperary, that two skilful persons from different parts of England, who had successively a fair course of trial, failed to make, from the milk produced from those fine pastures, a single cheese that combined the essential qualities of excellence of flavour and durability of keeping. Calves are seldom fattened except in the neighbourhood of large towns, where that meat is to be found of very fine quality. In the country parts it is the custom to slaughter the male calves when but a few days old; and the meat of them is sold to the lower classes, by whom it is distinguished by the name of slink veal.

The chief breeding counties for sheep are Roscommon, Galway, Clare, Limerick, and Tipperary. The flocks are usually managed by the herd, who attends the cattle; a regular shepherd, as in England, being seldom set over them. Folding is little practised, and the use of turnips for winter food is by no means general. In many parts sheep are kept for the sole purpose of supplying wool for the use of the owner's family. No county in Ireland equals Galway in the management of this valuable animal; and nowhere are finer flocks to be seen. There is reason to suppose that, in the time of Giraldus Cambrensis, the Irish breed of sheep was black. The introduction of the white breed of an improved kind is attributed to the English. Latterly much attention has been directed to the bettering of the stock, whether for the shambles, the wool comber, or the clothier, by judicious crossing. The merino sheep has latterly been brought over, and has been found to agree well with the soil and climate. On the mountains is found a breed similar to that of Wales, small, with nearly as much hair as wool.

The total number of sheep in the British isles is estimated by Mr Macculloch to have been, in the year 1830, as follows:—

England	26,500,000
Scotland	3,500,000
Ireland	2,000,000
United kingdom	32,000,000

The right of pasturage on mountains is frequently let to the inhabitants of a village in common, each of whom maintains on it a determinate stock of cows, goats, and sheep. In the apportionment five goats are considered as

Statistics. equal to a cow. Sheep are rated as goats, but are not so frequent; for milk is the chief object, and a ewe does not yield it so abundantly as a goat. Large flocks of this latter animal are to be seen amongst the mountains, where the cottier must be poor indeed who does not reckon one at least as part of his property.

Horses for agricultural purposes are seldom of great excellence. But a breed for general use, both for draft and saddle, is much esteemed; and blood-horses of high price and repute are bred in the rich pastures of the principal grazing counties. In general this animal is treated with less care and greater harshness than in England. The old Irish hobby, a small but excellent breed, supposed to be derived from a Spanish race, is nearly extinct; yet some vestiges of it are still to be traced in the western parts of Connaught, and in Kerry. In this latter county, a small breed of cows, very hardy, and excellent milkers, is still kept up.

Hogs are kept in great numbers. The native breed is tall, bony, and ill proportioned; but crosses from some of the most approved British stocks, particularly the Leicester, have been introduced, to the great improvement of the animal. In general the cottier's hog is the inmate of his cabin, a member of the family, upon whom the owner chiefly depends for the payment of his rent. Hence it acquires a docility of manners unknown elsewhere. Its food is invariably the potato. When fit for market it is either slaughtered in the provision markets of Cork, Waterford, Belfast, and Newry, or exported alive, chiefly to Liverpool.

Wakefield, in his observations on the state of tillage, classes the country into nine agricultural districts, according to the peculiarities of soil and culture. The first comprehends the flat parts of Antrim, the eastern side of Tyrone, and the counties of Down, Armagh, Monaghan, and Cavan. In these the farms are small, and spade cultivation common. Potatoes, oats, and flax, are the principal crops. The second district comprehends the counties of Londonderry and Donegal, the mountainous part of Antrim, and the north and west of Tyrone. Agriculture is in a more backward state here than in the preceding district. Wheat is little known. In the third, which is confined to the northern parts of Fermanagh, the system of tillage is better, and the farms larger. Wheat is largely planted, but oats form the great staple crop. The whole of the north-west of Ireland, comprehending Sligo, Mayo, Galway, Clare, with Roscommon and Longford, forms the fourth district. Oats is still the prevalent crop, but much barley is also raised in the districts near the sea. The plough is often drawn by four horses abreast. Illicit distillation is carried on here upon an extensive scale, and much of the land is leased to tenants in common, according to what is called the corn-acre system. In the fifth district, which comprehends Limerick, Kerry, the south-western and northern parts of Cork, and all Waterford, cultivation is not far advanced. The greater part is a grazing country. Where tillage prevails, the land is much subdivided, and the farms consequently very small. The sixth district includes the southern part of Cork. Spade culture is here frequent, the farms small, and hogs constitute the main dependence of the poor. The best farming in Ireland is to be seen in the seventh district, which takes in Tipperary, the Queen's, and King's Counties. Tillage is carried on in a systematic manner, and wheat forms an important part of the crop. The character of the eighth district, which comprehends Kilkenny, Kildare, Carlow, Westmeath, Meath, and Louth, much resembles that of the preceding, except that the system of tillage is not managed with so much neatness and precision. The farms are large, and the English mode of treatment adopted; but the details are executed in a more slovenly manner. Wexford, and the arable part of Wicklow, form the ninth district. Beans are largely cultivated. A very singular mode of ploughing may be seen here. One man leads the horses, another holds the plough, and a third sits on it to keep it down.

The preceding sketch shows that oats are the prevailing crop, then wheat and barley; flax on an extensive scale is confined to the northern counties. Potatoes are universally cultivated. It is the crop on which the great mass of the population depends for its subsistence; its failure, wherever it occurs, produces a famine. The outcry against the clumsy and defective construction of agricultural implements is every year less merited. In most parts much attention is paid to their construction; and, where they differ from those most in vogue in Great Britain, the cause can be traced to the peculiarities of the soil. The spade is narrower in the blade than the English, and longer in the handle. In many parts its use is supplied by a narrow spade, with a projection for the foot only on one side; it is called a loy. In cutting turf, a kind of double loy, called a slane, is used. Oxen are little employed in tillage. When used in the plough they are yoked sometimes by the horns, sometimes by the breast. The Scotch cart or dray, with two large wheels and a single horse, is to be found in every part, its structure having been found best adapted to a hilly country such as Ireland generally is. It has in a great measure superseded the old Irish car. In the mountainous parts the slide-cart without wheels is still employed. The ends of the shafts, which lie on the ground and are dragged on by the horse, being shod with iron, allow the vehicle to slide along with considerable facility. The fences vary extremely, according to the character of the soil. In the rocky districts in the north and west they are mostly dry-stone walls, sometimes of great thickness at bottom, being used as well for a means of getting rid of the numerous loose stones on the surface, as for the enclosing of the land. A mound, planted at top with furze, or gorse, is a common fence in those parts where fuel is scarce. In the more improved parts white thorn hedges are most usual. Lime and limestone gravel is the most general manure. It is often used mixed with turf mould. On the sea-coasts coralline sand and sea-weed are employed; the former is often conveyed to great distances into the interior. Paring and burning, though prohibited by statutory enactments, which impose a fine of ten pounds on the person practising it, is very frequent, and found, under judicious restrictions, to be highly salutary.

As the potato forms the main article of food for the general population of the country, it is evident that by much the greater part of the other crops raised must be disposed of in other countries, and therefore that the quantities exported will form no bad criterion of the progress of tillage, and of the crops to which it has been chiefly directed; but as this point comes more properly under another division of the work, the reader is referred to it, where he will find, in the statement of exports, an enumeration of the quantities of agricultural produce sent out of the country at different periods.

Fisheries. The peculiar natural advantages of Ireland with respect to the fisheries were long since noticed. Sir William Temple observes of them, that "they might prove a mine under water as rich as any under ground." Young asserts with truth, that "there is scarcely a part of Ireland but what is well situated for some fishery of consequence; and that her coasts, and innumerable inlets and creeks, are the resort of vast shoals of herring, cod, ling, hake, mackerel, &c. which might be converted into funds of wealth." Daniel, in his *Rural Sports*, speaking of the inland fisheries, says, that "the waters of Ireland abound in all that can invite an angler to their banks; they are more largely stored, and with fish of a better quality, than elsewhere in the

Statistics.

united kingdom." Such descriptions would lead to the conclusion that the fisheries were in a very flourishing condition. The contrary is the fact. The several attempts to establish them have failed, not certainly from want of fostering superintendence, but more probably from injudicious nurture, perhaps over attention. In the beginning of the reign of George III. the Irish parliament established a liberal system of bounties, particularly for the herring fisheries. The result of the experiment was the very reverse of what had been anticipated by the devisers of the measure. The following table shows that the import of herrings for nine years after the granting of the bounties, exceeded that of the nine preceding years by no less than 155,156 barrels.

Quantity of Herrings imported into Ireland for Nine Years before and Nine Years after the enactment of the Bounty System.

The chief seat of the herring fishery was along the north-western coast, from Lough Swilly to Broadhaven. To secure it, large sums were laid out in establishing stations for taking and curing the fish in the islands of the Rosses; but, after much expenditure, the fish deserted the shores about the year 1780, and the fisheries were of course abandoned. The Nymph Bank, on the southern coast, was discovered in 1736. It abounded with white fish, and a company was formed to take advantage of it; but the breaking out of the Spanish war three years afterwards put an end to the project. It afterwards remained unnoticed till 1801, when, through the exertions of Captain Robert Fraser, a company was formed for the special purpose of supplying the London market with fresh fish from it by means of well-boats; but the scheme proved abortive, apparently from internal mismanagement. In 1819, the attention of the legislature was again directed to the improvement of this source of national wealth, and a large sum was granted annually to commissioners, partly for the payment of bounties, partly for the erection of fishing piers, and partly for the issue of loans for building boats and providing fishing tackle. After twelve years' experience the grants were discontinued, and the commission was revoked. The following tables will serve to show the results of the efforts made to establish fisheries previously to the formation of the Fishery Board in 1819, and the effects of the exertions made by the commissioners, as stated by themselves in their reports.

Exports and Imports of Cured Fish at different periods before the establishment of the Fishery Board.

Whales and sun-fish are often seen off the western coast. The fishing of them has frequently been attempted, but always with loss. Seals are frequent along the rocky shores. They are occasionally shot; but as they are extremely wary, and must be struck on the head in order to kill them at once, they are seldom taken in this manner. They are sometimes, particularly the young ones, caught by moonlight, in the caverns where they sleep; but the attempt is very venturous. The old ones bite most furiously in defence of their young; and, as they are supposed never to let go their hold until they hear something crash between their teeth, the seal-catchers have bags, with charcoal quilted into them, fixed on their arms by way of defence. Most of the embouchures of the great rivers have salmon fisheries attached to them. That at Coleraine is particularly valuable; nearly all the fish caught there is sent fresh to Liverpool packed in ice. Eels are caught in large quantities in the large rivers, particularly after floods. As they do not take the bait, the usual mode of entrapping them is by stretching coarse hay ropes under water at the bridges, in which they are entangled while shooting down the stream. Shell-fish is abundant, particularly on the western and southern coasts. Oysters of much repute are raised at Carlingford; those from Burren and Lissadil on the western coast are also thought worthy of being transported across the island to Dublin. Muscle-beds are abundant, especially in the south; but they are sought after chiefly on account of the pearls occasionally found in them. In Cork the muscles are caught in sunny weather, at which time only they open their shells. The fisherman thrusts an osier twig into the aperture, the fish closes on it, and is drawn up. Pearls of the size of a pea, but seldom of good quality, are found in them.

Circulating medium.

The circulating medium in Ireland was, until lately, subject to a great variety of alterations. Without entering into the disputed question of the existence of a mint in Ireland established by the Ostmen or Danes, the first certain account of a mint there is that established in 1210, by King John, who caused pennies, halfpennies, and farthings to be coined and made current by proclamation. Further coinages were made by Henry III. and Edward I. The latter prince was the first who added the title of DOMINUS HIBERNIE to that of REX ANGLIE on his Irish coinage. It consisted of groats, halfpence and farthings. The first important alteration as to value was in the latter part of the reign of Edward III. who caused the ounce of silver to be cut into twenty-six deniers or pennies, instead of twenty, as before, which caused precisely the same depreciation of eight and one third per cent. in the Irish, as compared with the British currency, that lately existed, until the final assimilation in 1825. Henry VI. or rather the Duke of York, his lieutenant in Ireland, had mints in Dublin and Trim, in which both sil-

Statistics. ver and copper were coined. In the beginning of the subsequent reign of Edward IV. the value of the silver coins was raised to the double of its previous amount. The consequence was an enormous increase of price in all the necessaries of life; to remedy which, the Irish parliament enacted, that the master of the mint should strike, in the castles of Dublin and Trim, and in the town of Drogheda, five kinds of silver coins; the gross (or groat), the demigross, the denier (or penny), the demi-denier, and quadrant (or farthing); eleven groats to weigh an ounce troy, and each, unclipped, to pass for fourpence. A very few years afterwards, the price of silver was again raised so excessively, that the difference between the Irish and English groat was fifty per cent. in a pound of bullion. In the reign of Henry VII. the difference between the two coinages was one third. Soon after the accession of Henry VIII. the coin in Ireland was so clipped, defaced, and scarce, that the Earl of Surrey, then lord-lieutenant, sued for his recall, in consequence of the want of money to carry on the war against the Irish. Elizabeth ordered the ounce of silver to be cut into sixty pennies, so that the coin of that name was reduced in weight from the twentieth to the sixtieth part of an ounce. The total value of the money coined in Ireland by that princess is said to have been L.94,577. 19s. 6d. English, which, at the rate of sixteen pence Irish for a shilling English, amounts to L.118,222. 9s. 4½d. Irish. The Irish shilling, or harp as it was called, from the impression on its reverse, was worth ninepence English. By a proclamation issued in the fifth year of James I. the same proportion of values was continued. In 1613 English money was current in Ireland at an increased value; the English five-shilling crown-piece passing for six shillings and eightpence, and the other coins in proportion. The exchange between Dublin and London was at twenty-one shillings Irish for fifteen English, with sixpence or eightpence per pound extra, payable in London. By a proclamation in 1637, the name of Irish money was ordered to be abolished, and all payments reduced to English sterling money. About 1672, small change was so scarce in Ireland, that towns and private dealers were obliged to issue copper tokens. James II., on his arrival in Dublin in 1688, issued a proclamation, by which the English guinea was to pass current at L.1. 4s., the crown-piece at 5s. 5d., and all lesser coins in the same proportion. In 1690, he depreciated still further the value of the coin, by the issue of pieces of base metal, which were to pass at a nominal value far above their intrinsic worth; so that the coins issued of the nominal value of L.965,375 according to some, but, according to others, of L.1,596,799, were really worth no more than L.6495, estimating the metal at fourpence per pound. On the accession of William, this coinage was cried down. In 1725, the new gold coin of Portugal was made current in Ireland, the largest coin, or Portugal piece, being rated at L.4. About the same time, in consequence of the scarcity of small change, Wood obtained his patent for the issue of a copper currency, which was prevented by the literary exertions of Dean Swift in his celebrated publications called the *Drapier's Letters*. In 1780, the acts of parliament prohibiting the carrying of gold or silver into Ireland were repealed. At that time the value of the precious metals in circulation as specie, or hoarded, was estimated at L.3,000,000 Irish. No further legislative change took place until the assimilation of the Irish and English currency in 1825, previously to which, however, the want of a metallic circulation was so severely felt, particularly during some periods of the French war, that private bankers and other dealers issued notes or tickets for small sums, from five shillings down to twopence-halfpenny; and also copper tokens of a great variety of values and impressions. The character of the silver currency was much deteriorated during the same period, in consequence of the arrival of several regiments of English militia from Warwickshire and the neighbouring manufacturing counties, who, taking advantage of the defaced state of the Irish coinage of shillings, counterfeited them so ingeniously, that the country was for a time inundated with this description of base money. The evils of this combined pressure of the scarcity of legal and the abundance of counterfeit coin, was ultimately remedied by the issue of silver tokens, estimated at six shillings, tenpence, and fivepence, by the Bank of Ireland, which circulated freely until they were replaced by the issue of a pure standard coinage of silver from the royal mint.

Banking. The entire banking business of Ireland, until 1783, was in the hands of private individuals, who often issued notes to an amount not only far beyond their respective capitals, but exceeding, in a great degree, what the wants of the country required, or its credit could support. To remedy the evil effects of a system so pernicious, a national bank was established in that year, with similar privileges to those of the Bank of England in respect to the restriction of more than six partners in a private bank. The injury that Ireland has sustained from the repeated failure of banks may be mainly attributable to this injudicious regulation. The loss that the country has suffered by the failure of banks may be described in a few words. In 1804, there were fifty registered banks. Since that year, many more have been opened; but all have failed, one after another, with the exception of four in Dublin, three in Belfast, and a few that have withdrawn from business. In 1821, in consequence of the failure of eleven banks nearly at the same time in the south of Ireland, government made an arrangement with the Bank of Ireland, by which joint-stock companies were allowed to be established at the distance of fifty Irish miles from Dublin, in return for which concession, that company was permitted to increase its capital L.500,000; but, in consequence of several restrictions remaining unrepealed, no new company was formed until 1825, when the Northern Banking Company of Belfast began to act on the new system. In the same year the Provincial Bank of Ireland began business with a capital of L.2,000,000; and the Bank of Ireland has established branch banks in several of the larger towns. The capital of the Bank of Ireland at its commencement amounted to L.600,000. It has been since increased at different periods; and in 1821 it amounted to L.3,000,000. At present no bank with more than six partners can be established within fifty Irish miles of Dublin; nor can such bank draw bills on Dublin for less than L.50, or at a shorter date than six months, which is a virtual prohibition of the drawing of such bills. The Bank of Ireland draws on London at twenty days date, and discounts at the rate of five per cent. Its charter expires in 1838.

The following table exhibits the amount of the issue of Bank of Ireland notes, and the highest and lowest aggregate amount of Bank of Ireland notes and post bills issued, as far as can be collected from official documents :—

Issue of Bank of Ireland Notes and Post Bills for every Fourth Year from 1798 *inclusive.*

Years.	Bank Notes.				Post Bills.		Total of Notes and Post Bills.

In the Provincial Bank, twenty-five per cent., or L.500,000, has been paid up. Its head is in London, but it has offices in all the large towns of Ireland. The business of the branch banks is managed, under the control of the directors in London, by the managers, with the aid of two or more residents in the district, who must be holders of ten shares each. This bank has had several severe runs to contend against. In 1828, L.1,000,000 in gold was sent from England to maintain its credit. Its notes are received in the treasury in payment of taxes; and it is the bank of the excise, post-office, and stamp-departments, in all places beyond the restricted limit. The dividends have been at the rate of four, five, and, since December 1832, of six per cent. Its stock is at a high premium. The Northern Bank transacts business on similar principles with the Provincial, but on a smaller scale. The Hibernian Joint-Stock Loan Company was formed by some Roman Catholic gentlemen and merchants, in consequence of their exclusion from seats in the direction of the Bank of Ireland. Its nominal capital was L.1,000,000, in 10,000 shares, of which twenty-five per cent. was paid in. It issues no notes, and has no branch offices. In 1824, the company obtained an act, which gave them some additional facilities in transacting their concerns. Two new joint-stock banking companies were commenced in the year 1833; the one, called the Agricultural and Commercial Bank of Ireland, is managed in Ireland, and rests on Irish capital; the other, called the National Bank of Ireland, has a proprietary in London, who have contributed a large capital on the principle of advancing to any bank formed in connection with it in Ireland, a sum equal to that subscribed there, and receiving half of the profits of the joint capital. Both of these banks have branches in some of the great towns. Private banks are now to be met only in Dublin, where there are but four. Ireland has but few manufactures and little commerce, and banks abound only in wealthy and commercial countries. Another striking circumstance is the vast proportion of notes under five pounds issued by the country banks. This is accounted for by the smallness of the transactions, and the peculiarities of Irish trade, which in the north is chiefly confined to the domestic manufacture of linen; and in the south to the provision trade, the supplies for which are furnished, in consequence of the great subdivision of land, by a number of dealers, each of whom can furnish a very limited quantity. The fairs and markets are attended by multitudes of people, bringing each his butter, corn, and poultry, for sale, few of whom individually take away to the amount of five pounds.

A reference to the preceding table of the issue of Bank of Ireland notes will confirm this position, by showing that the increased issue of that bank, since the commencement of notes under five pounds, has arisen from the increased number of those under that value.

The system of savings' banks was introduced from Scotland in 1817, when an act was passed, by which a fixed interest of L.4 per cent., resting upon public security, was granted to the depositors. This rate was in 1828 reduced to three per cent., in consequence of the influx of deposits from persons who thereby derived a larger interest from their lodgments than what was then attainable from funded security. The confidence at first excited in favour of this mode of securing small sums has been latterly considerably diminished, from the discovery, that though the interest payable is secured by act of parliament, yet the management, being lodged in the hands of private individuals who undertake it ostensibly from benevolent motives, is under no effective check beyond that of the general character of the directors. Several instances have occurred of losses to a considerable amount, from the negligence or misconduct of the managers. The following

Statistics. tables show the progress of the system as far as can be ascertained by public documents; the first showing the gross amount of deposits and deductions to the latest return published; the latter the rates of the deposits at two periods, by which not only the progress of the system, but the proportional number of contributors of different pecuniary means, may be conjectured.

Roads. The internal traffic of the country is carried on chiefly by wheel-carriage roads. Canals are few, and railways almost unknown. The great roads are mostly kept up by turnpikes, against which there was, until lately, a violent and just outcry, as the outlay upon them did not at all correspond with the amount of tolls collected. Latterly most of them have been placed under the control of the post-office, which lets them out to contractors. Their condition, both as to lines of direction and mode of construction, is excellent. The limestone, which is the general substratum of the greater part of the country, is the best material for their formation; and the system now so generally known and highly appreciated under the name of macadamizing was long and successfully practised in many of the leading lines of road in Ireland before it was thought of in Great Britain. Young remarks upon this peculiarity as early as the year 1779. "For a country," says he, "so very far behind us as Ireland to have got so suddenly the start of us in the article of roads, is a spectacle that cannot fail to strike the English traveller exceedingly. I will go here; I will go there; I could trace a route upon paper as wild as fancy could dictate, and everywhere I found beautiful roads, without break or hindrance, to enable me to realize my design. But from this commendation the turnpikes in general must be excluded; they are as bad as the cross roads are admirable." The cause of this eulogy is to be traced to acts made on the subject from the time of Charles I. till the beginning of the reign of George III. Before that time the roads were constructed and repaired, like those in England, under the miserable police of the six days' labour. The new law totally changed the arrangement. The system according to which the cross roads, or, as they are called, the presentment roads, are made, is this: The part to be acted upon is measured by two persons, who swear to the measurement, to their opinion of its utility, and to its probable expense. A certificate to this effect is signed by the measurers, the overseers who propose to undertake the work, and the justice before whom the oath is taken. It is then sent in to the grand jury at the assizes, and if approved there, the work is undertaken by the overseers at their own expense, and must be finished before the ensuing assizes, when, on a certificate upon oath that the money has been honestly expended, it is passed by the grand jury, fiated by the judge of assize, and paid forthwith by the county treasurer. In like manner, bridges, jails, houses of correction, and other public works, are built. The expense is defrayed by a tax on the lands, paid by the occupying tenant, either by the acre or by the plough-land or town-land. In the latter case, as these denominations are of very unequal dimensions, the tax falls very unfairly upon the holders of the land. The restriction upon a wanton outlay of money, either in consequence of an unnecessary line of road, or an exorbitant estimate of expense, is by traversing, or opposing, the presentment in the first case, that is, by denying the allegations in the certificate. The presentment is then laid by till the ensuing assizes, and in the intermediate time inquiries are made respecting the conflicting statements. In the latter case, payment is suspended until the case is cleared up and proved. The good effects of this system rest upon the principle, that when individuals act for the public alone, the public is likely to be negligently, and therefore badly served; but when their own interest as well as that of the public is concerned, good is likely to be done. For a few years after the passing of the act, the good roads were found all leading from the mansions of the principal gentry in the counties, as rays from a centre, with a surrounding space through which there was no communication; but every year brought the remedy, until in a short time those rays, proceeding from so many centres, met, and the communication was complete. At first, roads were, like bridges, paid out of the common stock of the county, but afterwards they were charged upon the barony through which they were made. By subsequent acts, narrow mountain roads, and foot-paths along the sides of the greater roads, were constructed upon the same principle. The exorbitancy of expense, arising from the power of imposing the tax having been vested in the hands of the great landed proprietors as grand jurymen, whilst the payment came out of the pocket of the poor occupier, was the less felt, except in some extreme cases, because the money was expended among those who paid it, and gave employment to many hands that otherwise would have been pining away in idle destitution. Still, however, it must be acknowledged, that complaints against what is called jobbing were, and still continue to be, general, and too often upon solid grounds.

Inland navigation, &c. With respect to canals, the manner in which Ireland is circumstanced in this respect may be most fairly estimat-

Statistics.

ed by a view of the following table, which exhibits the relative proportion, or rather disproportion, of the means of internal communication, by means of inland navigation and railways, in that country and in England.

	Ireland.	England.
Acreable contents	20,499,500	37,094,960
Population in 1831	7,734,365	16,537,398
Canals......miles	280	2400
Navigable rivers.....miles	380	2000
Railways......miles	$5\frac{3}{4}$	400

The idea of improving Ireland by means of inland navigation is attributable to the unfortunate and misguided Earl of Strafford, who had the sagacity to perceive that the general flatness of the country, and the abundance of lakes, waters, and bog, were very favourable to it. Yet no parliamentary steps are on record respecting the subject until 1703, when bills were brought in to make the Shannon navigable from Limerick to Jamestown in Leitrim, for the rivers Barrow and Boyne, and for connecting Newry with Lough Erne. No further steps were taken till 1709, when the subject was revived. In 1715 a company for rendering the Shannon navigable was formed, under an act which also gave general powers for similar undertakings elsewhere. Many projects were started under the provisions of this act. The following is a summary of their results:

1. From Dublin to Banagher on the Shannon; accomplished by the Grand Canal.
2. The Barrow, with a canal thence to join the Grand Canal; accomplished.
3. The Glyn and Bann, from Newry to Coleraine; effected as far as Lough Neagh by the Newry Canal.
4. The Nore and Brosna, from New Ross to the Grand Canal; unaccomplished.
5. The Liffey and Greece, from Dublin to Carlow; partially effected by the Kildare branch of the Grand Canal.
6. The Blackwater, from Youghal to Newmarket; effected as far as Lismore.
7. The Foyle, Finn, Derg, and Mourne, from Derry to Omagh; effected to Strabane.
8. The Boyne, from Drogheda to the Grand Canal; the river made navigable to Navan.
9. The Suir, from Waterford to Thurles; a towing-path made to Clonmell.
10. The Lee, from Cork to Macroom; some locks made, but to no purpose.
11. The Erne, above Lough Erne; unattempted.
12. The Maig, from Limerick to Cork; unattempted.
13. A line from Sligo to Carrick-on-Shannon; unattempted.
14. A line through Lakes Corrib and Mask, from Galway to Killala; unattempted.
15. The Slaney, from Wexford to Baltinglas; unattempted.
16. A line from Galway to the Shannon; unattempted.
17. The Inny, from Lough Shillin to the Shannon; unattempted.
18. The Suck, from Castlerea to the Shannon; unattempted.
19. The Bandon, from Kinsale to Dunmanway; unattempted.
20. The Laune, from Newcastle to Castlemaine; unattempted.

After a lapse of fourteen years, it was found that works of such magnitude could not be carried into effect without public aid; a fund was therefore formed by parliament from taxes on wheel-carriages, cards, dice, and wrought plate. The amount of the income thence arising amounted in 1735 to L.3000 per annum, in 1740 to L.4000, and in 1750 to L6000. For nineteen years the whole fund was applied to the navigation from Newry to the Tyrone collieries. The committee for the improvement of tillage having reported that inland navigation was the most effectual means for its increase, the lines of the present Grand and Royal Canals were struck out, but the public money was applied solely to the former of these. In 1771 the board of inland navigation was empowered to transfer the property of any canal in progress to a local company which would subscribe towards its completion; and several additional grants of money were made in aid of such companies; but in 1789 it was found that the board had involved itself in debt to the amount of upwards of L.26,000, whereupon it was dissolved, the payment of debts secured by debentures, and the navigations transferred to local commissioners. In the same year parliament resolved to grant one third of the expense to any new undertaking of this kind; and from thence to the union many large grants were made on this principle. The two great canal companies, during the same period, were induced to undertake an expensive system of wet docks in Dublin, which greatly embarrassed their funds, without a prospect of adequate remuneration. At the union, L.500,000 were granted for inland navigation generally, and for some specific lines of works, to be under the control of a board. Since that period to 1812, L.213,000 were further granted to them. The principal objects of expenditure were the Grand and Royal Canals, the Shannon and the Barrow Rivers, the Newry and Tyrone Canals. The board has also, since 1810, caused several surveys to be made of lines between the Shannon, Barrow, Suir, and Grand Canal, and also towards Loughs Erne and Neagh. Various minor lines have likewise been pointed out, in consequence of the general survey of the bogs; so that it may truly be said, that a more perfect knowledge of the levels and waters of Ireland has been obtained than of any other country in the world except Holland.

To proceed to some of the details of the works that have been completed: The Grand Canal commences near the embouchure of the Liffey, where it has floating docks with sixteen feet depth of water, and capable of containing 400 sail of vessels, with three entrance-locks, and three graving-docks. It sweeps round thence by the southern verge of the city westward for eighty miles, to the Shannon at Banagher, with branches to the Barrow at Athy, and some minor ones. The summit-level is 240 feet above the level of the sea, and 160 above the Shannon. The commodities conveyed on it are flour, grain, potatoes, turf, coal, manure, brick, stone, flags, slates, and assorted merchandise. Its revenue in 1813 amounted to L.90,000, but since the peace it has diminished considerably. A branch of this canal was carried on westward of the Shannon to Ballinasloe in 1828, being a distance of fifteen and a half miles.

The Royal Canal extends from Dublin westward to the Shannon, nearly parallel to the Grand Canal, and for a long part of its course seldom more than ten miles distant from the latter. It begins on the north side of the Liffey, with which it communicates by a sea-lock, opening into a floating-dock capable of containing twenty-seven sail of shipping; and thence by the Broadstone, where there is a harbour, to Tarmonbarry in Longford; its total length being eighty-eight miles. The summit-level is 307 feet above the sea. The company by which this navigation was undertaken having become insolvent, it lapsed into the hands of government, by whom it has been completed and rendered available. The principal commodities conveyed by it are grain, meal, flour, butter, potatoes, turf, timber, bricks, and stone. In 1828, during a severe scarcity of potatoes in Leinster and the south of Ireland, whilst there was a superabundance in Connaught, 22,292 tons were brought to Dublin from the latter province by the Royal Canal, which greatly alleviated the distress of the poor in the other parts. The general tonnage on these two main canals has been as follows:—

Years.	Grand Canal.		Royal Canal.	
	Tonnage.	Amount of Toll.	Tonnage.	Amount of Toll.
	Tons. Cwts.	L. s. d.	Tons.	L. s. d.
1821	142,622 ...	32,517 13 10½	108,933	8,654 17 4

1831	237,809 15	36,735 12 3	129,844	12,729 6 1

Of the lesser artificial lines of inland navigation, the Newry Canal is the most important, and was the first completed. It is navigable from the tideway at Fathom, to Newry, for vessels of nine or ten feet draught; and thence to the Bann, where that river becomes navigable for barges of sixty tons. Its summit is sixty-five feet above the sea. The navigation is carried on in the Bann for twelve miles to Lough Neagh, which is navigable through an extent of fifteen miles by eleven. The Lower Bann, from Lough Neagh to the sea below Coleraine, is yet unnavigable, from obstructions in its course.

The Lagan navigation extends from the tideway at Belfast, partly in the river, partly artificially, to Lough Neagh, a distance of twenty miles. It is the only undertaking of the kind which has been maintained by local taxes, assessed upon the neighbouring districts at their own request.

The Tyrone Colliery Canal extends from Coal Island in Tyrone, four miles to the Blackwater, and thence by a short cut into Lough Neagh, which thus forms the receptacle for three branches of inland navigation. The communication from the colliery basin to the mines is by a wooden railway.

A new line of inland navigation, under the name of the Ulster Canal, is now in progress. Its object is to connect Loughs Neagh and Erne. The workings have been carried on from the former of these points to Tullybrick Lake in Armagh.

The river navigation, commencing from Dublin, may be summed up as follows: The Liffey is navigable merely to the western extremity of Dublin city, and that only from half flood. The Slaney is navigable for barges from Wexford to Enniscorthy, a distance of nineteen miles. On the southern side of the island, the Barrow has been rendered navigable from the tideway at the Scars, below St Mullins, to Athy, a distance of forty-three miles; the total fall is 172 feet. It is partly a river, partly a still water navigation. The Nore, a branch of the Barrow, is navigable for barges from New Ross to Thomastown. The Suir, another branch, admits vessels of the largest draft at Waterford, and thence is navigable for sloops to Carrick, and for barges to Clonmell. The southern Blackwater admits vessels of 300 tons over its bar, and sloops can proceed eight miles up the river to Dromore. A navigable canal has been cut by the Duke of Devonshire, from Cappoquin to Lismore, three miles. Three miles of canal were also made above Mallow. The Lee admits vessels of 200 tons as far up as the city of Cork, and barges a short distance farther. The Bandon is navigable from Kinsale to within three miles of Bandon. On the western coast, the Laune and Main in Kerry uniting, fall into the head of Dingle Bay. They admit sloops to Castlemaine. The noble river of the Shannon, which, if properly treated and cleared of its impediments, might be called the great aorta of Ireland, is navigable, but with frequent interruptions, from Limerick, for 230 miles. The Maig, one of its branches, admits boats as far as Adare; and the Fergus, which discharges itself into its estuary, has been rendered navigable for boats as far as Ennis. The Moy, in Mayo, admits small vessels from Killala to Ballina. The only navigable river on the northern coast is the Foyle; it is navigable by nature for nine miles to St Johnstown, and thence by the assistance of art for four miles farther to Strabane. Proceeding north about to the eastern coast, the only river to the north of Dublin is the Boyne, in which, by the attention paid to clear its channel, vessels of considerable burden can run up as far as Drogheda, four miles from its mouth. The navigation is continued thence for boats in the bed of the river to Slane, and beyond that by artificial means sixteen miles further, to Navan and Trim. The total ascent from the former to the latter of these places is 190 feet. The following table affords a summary view of the length of the chief lines of inland navigation, and of the expense at which they have been formed.

Comparative Rates of Expense per Mile, of the several Navigations in Ireland, with Rate of Lockage on each respectively.

Lagan Navigation	22	$8\frac{1}{3}$	4,363	96,000	

Statistics.

Besides these river navigations, and that of Lough Neagh already noticed, Lough Corrib is navigable from Galway for boats for nearly fifty miles. The chief trade is in turf, lime, and grain to Galway. The Erne becomes navigable at Belturbot, whence there is a navigation through the lakes, but obstructed at the gut of Enniskillen by weirs. The free passage from the lakes to the sea is prevented by the salmon weirs at Ballyshannon.

The only rail-road is that between Dublin and Kingstown, a distance of five miles and three quarters. It is formed on the model of that between Liverpool and Manchester. It was opened in 1834, and promises to be very productive, chiefly by the conveyance of passengers. Its shares are at a premium of upwards of a hundred per cent.

Cattle trade, &c.

The cattle trade is chiefly transacted at fairs, of which by far the most important is held at Ballinasloe in Connaught. There are two annual fairs; that of October regulates the transactions as to live stock in black cattle and sheep for the ensuing year. The extent of dealings can be estimated by the subsequent tables. The sheep and heifers sent thither are from three to four years old, the bullocks from four to five. The latter are mostly lean, and are kept for a year on the rich pastures of Leinster before they are thought fit for the Dublin or Liverpool market. The decline in the number of cattle and sheep in the latter years, stated in the table, is attributed partly to the increase of tillage cultivation, caused by the great increase of the population, and the consequent continual subdivision of land, and partly to the increased demand for cattle and sheep in several other fairs.

Number of Sheep and Black Cattle Sold and Unsold at the October Fairs at Ballinasloe, for every Fourth Year from 1790 to 1834 both inclusive.

Years.	Sheep.			Black Cattle.		
	Sold.	Unsold.	Total.	Sold.	Unsold.	Total.

1834	57,810	8,904	66,714	7,521	2,116	9,637

The traffic in cattle slaughtered for exportation is transacted in the towns in which the trade is carried on, whither the animals are sent from great distances. The principal marts are Cork, Limerick, Waterford, and Belfast. The corn sold is either purchased by factors or sent to the mills in the neighbourhood, where it is ground and disposed of for domestic consumption or for export. The extent and progress, both of the provision and corn trade, will best be ascertained in the tables of exports under a subsequent division of this article. The linen trade is carried on chiefly at the weekly markets held in the larger towns of the northern province, to which the manufacture is mostly confined.

Trade and commerce.

The external trade of Ireland branches out into two great divisions, the cross-channel trade with Great Britain, and the commerce with foreign nations. The progress of domestic navigation will appear best from the first of the following tables, containing a summary, in periods of ten years each, of the number and tonnage of ships built in Ireland, and of the number and tonnage of those belonging to the several ports of Ireland; while the relative importance of each port, as respects its commercial character, will appear from the second, which contains a specification of the number of vessels registered in each of the ports of Ireland in each of the years specified.

Statement of the Number and Tonnage of vessels Built in Ireland, and of the Number and Tonnage of those that belong to the several Ports there, arranged in totals of Ten Years.

Years.	New Vessels.		Vessels Registered.	
	Vessels.	Burthen.	Vessels.	Burthen.

The progress of the general navigation of Ireland with other countries may be inferred from the following table, which also affords a view of the outlets for Irish commerce at the periods specified. The official returns previously to the union do not state the number or tonnage of the vessels which cleared out from Ireland for foreign parts. What has been published is sufficient, however, to show the great preponderance of the trade with Great Britain over that with all the world besides. The accounts could not be stated according to any cycle of years, in consequence of a chasm in the official documents from 1806 to 1817.

Number of all Vessels, British, Irish, and Foreign, entered inwards into Ireland.

The preponderance of the trade with England over that with all the rest of the world is still further illustrated by the following tables of imports and exports, which also exhibit a view of the principal articles, both of the cross-channel and foreign trade, and of the increase or diminution of the several articles of which it consists:—

Another view of this interesting illustration of the importance and value of the commercial ties which connect together these two great portions of the united kingdom, may be had from the following tables, the two first of which exhibit the number of vessels that entered and quitted the ports of Ireland during the period therein mentioned; the third shows the progressive increase of the interchange of the commodities of both islands by the cross-channel trade.

Vessels entered Inwards into Ireland.

Average Amount of Imports and Exports between Great Britain and Ireland.

	Imports into Ireland.	Exports to Great Britain.
1749 to 1759, ten years	L.1,015,305	L.1,274,569
1759 to 1769, ten years	1,367,573	1,719,575
1769 to 1779, ten years	1,823,183	2,405,747
1779 to 1789, ten years	2,286,562	2,710,039
1789 to 1799, ten years	L.2,923,321	L.3,816,018
1799 to 1809, ten years	4,317,828	4,114,704
1809 to 1819, ten years	4,787,434	5,722,242
1819 to 1825, five years	5,046,389	6,450,803

The imports may be considered as almost wholly intended for home consumption, either as materials of manufacture, or for the immediate use of the people, as the quantities imported for re-exportation, though increasing

Statistics. of late, bear a very small proportion to their total amount. The principal articles imported in a raw or unwrought state are, coal, iron, flax-seed, flax, hemp, ashes, cotton wool, timber, deals, staves, tallow, bark, and silk. The importation of these for every tenth year, until the termination of the official returns, will give a general idea of the quantities imported, and their increase or diminution.

Raw Material of Manufacture imported from all parts in 1773, and every Tenth Year after.

The exports from Ireland are chiefly the agricultural produce of the country, with a few manufactured articles produced from them, without having undergone many processes of manipulation. The articles forming these exports, and the increase or decrease of value of each description sent into Great Britain after a lapse of ten years, terminating at the latest period of which official documents afford information, may be deduced from the following table:—

Species of Exports to Great Britain, and the value of each description, at two periods of Ten Years distance.

	1815.	1821.
Bacon and hams	L.378,161	L.519,049
Beef	148,452	126,714
Butter	463,130	621,245
Grain, meal, &c	683,557	1,700,963
Cotton goods		356,819
Cows and oxen	37,252	146,935
Flax, dressed and undressed	47,448	101,424
Hides	10,241	7,731
Horses	16,845	39,832
Lard	21,595	44,998
Linens	1,628,659	2,111,696
Paper		32,546
Pork	227,561	167,879
Sheep		16,236
Skins	25,162	9,090
Spirits, Irish	40,325	55,787
Swine		32,959
Wool	33,774	29,427
Yarn, cotton		20,980
—— linen	75,247	26,234
Other articles	264,786	376,018
	L.4,167,597	6,544,575

Taking the article of linen from among those quoted in this table, to show the increasing ratio of the cross-channel trade, and its superiority over that with all the rest of the world besides, the following totals of the number of millions of yards exported to Great Britain and elsewhere will serve as a satisfactory illustration of the fact.

1801.	1805.	1809.	1815.	1817.	1821.	1825.
37	43	37	39	56	49	55
34	40	33	35	50	45	52½
3	3	4	4	6	4	2½

The facilities for promoting this mutual intercourse, to which both countries owe so much, have been augmented to an extraordinary degree by the discovery of open-sea steam navigation. The earliest attempt at establishing a company for this purpose was made in Dublin about the year 1816. Two small vessels were fitted out; but the construction of their machinery was faulty, their dimensions were too small, and the effort proved abortive. Now, the trade, with the exception of that of coal, is chiefly carried on by means of steam.

Many of the principal features of the character of the people may be deduced from the preceding summary of their history, and of their present state. In appearance, the peasantry are of full size, strong, vigorous, athletic, healthy; capable of much labour, but averse from long continued exertion. In moral and intellectual qualities they are ardent in their affections, extreme in the indulgence of their passions both of love and hatred, easily roused, desperate and daring to excess when excited, but also quickly dispirited and deeply desponding under failure; vivacious, social, much attached to home, dreading expatriation more than death; addicted to rural sports and amusements; fond of music and song, and still more so of dancing; adhering with inviolable fidelity to their engagements to each other, but lax in their sentiments of moral obligation towards those whom they consider as their enemies; of quick, shrewd intellect, admirers of literature, and vain of their own acquirements in it. This general description, both of external and intellectual qualities, is varied by striking shades of difference in the different parts of the country. Derived from distinct aboriginal stocks, the inhabitants of each province, particularly those in the extreme and less-frequented districts of each, exhibit marked traits of their parentage, in person, physiognomy, customs, and language. In the north-eastern part of Ulster, the Scotch features, dialect, manners, and dispositions, are strikingly prevalent. In the south of Leinster the peasants still retain much of the old English language and customs. In Kerry, the Spanish descent is clearly to be traced in the personal appearance, the dress, and the style of building prevalent there. In Connaught and the north-west, the vestiges of the aboriginal Celt is still prominently conspicuous. The Irish language is spoken in all parts except in the Welsh colony in Wexford, and in that of the Scotch settlers in the east of Ulster, but with marked variations of dialect and tone in various parts. That of the mountainous districts of Donegal is said, by those deemed to be adepts in the study of national philology, to be the most pure. Few countries exhibit such a contrast in the architectural construction of the habitations of the higher and lower orders. The mansions of the nobility and great landed gentry are capacious, splendid, and fitted up with every appendage of rural luxury. Those of the middling classes, whose great ambition it is to imitate, and if possible to rival, the style of living of their superiors, are generally neat and elegant. The glebe-houses of the Protestant clergy exhibit every appearance of English comfort. The cottages of the peasantry are seldom more than huts of earth, covered with straw, with one or two windows. In the mountainous districts, where timber is scarce, they are miserable in the extreme. The clothing of the great body of the people is home-made frize and linen. The former material is generally dyed with some peculiar tint that marks at sight the locality of the wearer. Latterly, cottons have superseded to a great extent the use of linen, particularly amongst the women. The universal food is the potato, aided occasionally by bacon, and, in the maritime parts, by fish. Milk is the usual beverage. Indulgence in spirituous liquors has long been imputed to the Irish as a national vice. There is a very trite proverb throughout the country, that where there is smoke, there is fire. Even though true, it admits of the qualification, that where there is most smoke, there is often but little fire. A reference to facts and printed documents will show that the quantity of spirits consumed in Ireland, compared with that in the other divisions of the united kingdom, does not bear out the sweeping and prevalent charge of excessive inebriety. Parliamentary documents lately published furnish the following statement of the number of gallons of spirits of every kind that paid duty in each part of the united kingdom.

	England.	Scotland.	Ireland.	Total.
	Gal.	Gal.	Gal.	Gal.
Rum	3,306,650	111,169	27,358	3,345,177
Brandy	1,326,204	37,075	25,360	1,388,639
Geneva	13,075	6,075	2,264	21,632
Other foreign spirits	8,003	1,534	364	9,901
Total foreign	4,554,086	155,917	55,346	4,765,349
Home-made spirits	7,654,465	6,045,043	9,708,462	23,407,970
General total	12,208,551	6,200,960	9,763,808	28,173,319

According to the data here afforded, the average consumption of spirits, compared with the population of each portion of the united kingdom, will be as follows:

	England.	Scotland.	Ireland.	Total.
Population in millions	13	$2\frac{1}{4}$	$7\frac{3}{4}$	22
Spirits in millions of gallons	$12\frac{1}{4}$	$6\frac{1}{4}$	$9\frac{1}{4}$	28
Average consumption per man in gallons, nearly	1	$2\frac{3}{4}$	$1\frac{1}{4}$	$1\frac{1}{4}$

So that England being the standard of unity, the excess of consumption is but one fourth in Ireland, whilst it rises to one and three fourths in Scotland. A deduction, however, must be made for the large quantity of spirits sent, by some strange anomaly in the management of the excise, from Scotland, both into England and Ireland, notwithstanding the lower rate of duty here; for which, if due allowance be made, it is probable that the average consumption of ardent spirits will be found to be nearly equal throughout all parts of the united kingdom, and that the character of excess which still adheres to Ireland may be accounted for partly from prejudice, which is apt to cling pertinaciously to long-established and old opinions, and partly to the fact that the indulgence on the part of the lower classes is more public.

As far as drunkenness and crime are connected in the relation of cause and effect, the comparative view of convictions in Ireland shows that crimes of atrocity, which are most likely to be the result of passions excited by the excessive indulgence in spirituous liquors, are on the decline. The number of executions is considerably diminished since 1822, and of those which have taken place, many, if not most, were for murders connected with political circumstances. The following table exhibits a view of the criminal offences from 1822 to 1834 inclusive.

	1822.	1823.	1824.	1825.	1826.	1827.	1828.	1829.	1830.	1831.	1832.	1833.	1834.

Statistics.

Other official documents for last year tend to show, as far as the number of places for vending spirits can exhibit it, that their sale is more general in England than in either Scotland or Ireland, whilst in the last-named portion of the kingdom the consumption of beer is evidently on the increase. Of the following summaries the former gives the number of retail spirit-licenses issued last year, the latter the quantity of malt used by brewers.

	England.	Scotland.	Ireland.	Total.
1.	47,312	16,278	18,416	82,006
2.	15,837,409	997,771	2,055,326	10,890,506

The following table of the consumption of articles of foreign luxury may serve as a criterion of the progress of refinement throughout the country. In drawing conclusions from it, the increase of the population at each period here stated should be kept in mind.

Quantities of Articles Imported for Home Consumption in 1784, and for every Fourth Year after.

Year.	Sugar.	Tea.	Coffee.	Wine.	Brandy and Geneva.	Rum.	Tobacco.

The statement of savings' banks already given may also serve as another element of calculation in forming the same estimate. Friendly societies, so largely spread over England, and protected there by several statutory enactments, seem to have taken but little root in Ireland. The following return shows the number of these societies, whose regulations are filed with the clerks of the peace, according to the law, from 1792 to 1832, a period of forty years, viz. England, 17,365; Scotland, 2144; Ireland, 274.

Education.

The efforts to improve the state of the people by religious and literary instruction have been numerous and extended. For some centuries after the settlement of the English, these efforts were, however, conducted on a principle as unjust as impolitic. All attempts at bettering the condition of the people were limited to the English settlers or the inhabitants of the pale, those of the rest of the island being treated as enemies. To such a height was the distinction carried, that whilst the murder of an Englishman was death, that of a native was suffered to go unpunished, provided it could be proved that he was mere Irish, and not one of the five bloods of the O'Neills, O'Melaghlins, O'Connors, O'Briens, and M'Murroughs, who were admitted by special favour to the privileges of English subjects. It was not till the reign of James I. that the whole of the island was allowed to participate in the protection afforded by English law.

The machinery used for diffusing religious instruction has already been developed in the account of the ecclesiastical state of the country. That of the literary instruction remains to be stated. It may be arranged under three heads; collegiate institutions for the higher departments of science and literature; academies and schools for rudimental instruction in the same studies; and primary schools for affording the first elements of knowledge to the great mass of the population.

The first attempt at founding an university after the arrival of the English was made by John Leek, archbishop of Dublin, who obtained a papal bull for the purpose in 1311, which was carried into effect in 1320 by Alexander Bicknor, his successor. The disturbed state of the country prevented its success. Little more is known of it than that, after lingering through an existence of some time, it died away. Another similar attempt was made, with similar success, at Drogheda, where an university was founded by act of parliament in 1465, with the same privileges as that of Oxford. The next attempt was more happy. In 1593 the university of Trinity College, Dublin, was opened in the buildings of the dissolved monastery of All-Hallows. It still continues to be the sole university in Ireland. Another was opened by James II.; but after his flight it was handed over to Trinity College, and soon afterwards finally closed. The celebrated Henry Flood left a bequest for the endowment of a college after his death; but the legacy lapsed, from a neglect of applying it within the proper time. In 1810 the inhabitants of Belfast opened a collegiate institution for scientific and literary instruction by private subscription. It has been sanctioned by act of parliament, and receives a liberal grant of public money; but as it has not been privileged to grant degrees, it cannot be ranked as a university.

With respect to the second class of places of public education, an act of Elizabeth required that a grammar-school should be maintained in every diocese, by the contributions of the bishop and beneficed clergy. James I. improved on the idea, by vesting large tracts of forfeited lands for the maintenance of similar schools. His example was followed by Charles I. Erasmus Smith, also, one of the adventurers who obtained large tracts of land during the time of Cromwell, applied some of his property to this purpose. Classical schools were also endowed by other private individuals. The schools of royal foundation were those of Armagh, Dungannon, Enniskillen, Raphoe, Cavan, Banagher, and Carysfort. Those of Erasmus Smith's, and other private foundations, were, Drogheda, Galway, Tipperary, Ennis, Navan, and Ballyroan. The diocesan schools never exceeded seventeen out of the twenty-two dioceses.

The primary schools owe their foundation to an act of Henry VIII., which bound every incumbent of a parish by oath to maintain a school therein to teach the English language. The bond was neglected by many, and observed with culpable laxity by most others. The statute having fixed upon forty shillings as the minimum of the teacher's salary at the time of its enactment, the incumbent, regardless of the great subsequent depression of the value of money, deemed his duty to be fulfilled and his conscience cleared by paying that annual stipend to his parish-clerk, or some other person who professed to teach in the parish. Soon

Statistics. after the revolution, a project was started and eagerly followed up by the established clergy, of founding schools, in which the children of the poor should be instructed in the rudiments of literature, as well as in useful works, and also maintained at the public expense. To these laudable objects was also added that of converting them to the Protestant doctrine. These schools being incorporated by act of parliament, received the name of charter-schools. They were long a favourite object of interest to the legislature, which annually voted large sums for their support, in addition to those procured by donation or bequest. Notwithstanding several essays on general education were subsequently written, and the subject brought before parliament at different times, nothing further was practically attempted till 1819, when a voluntary society was formed in Dublin, for the avowed purpose of instructing the poor, without interfering with their religious opinions. The society was at first generally supported; and being aided by liberal grants of public money, promised fair to achieve its professed object. But a stipulation introduced into its regulations shortly after its commencement, requiring the Bible to be used as a school-book, aroused the suspicions of the Roman Catholic clergy, who excited such a distaste to it throughout the country, that it was found expedient to withdraw the grant, and to transfer the management to another body. The important duty of providing literary instruction to the great body of the people is now delegated to a board, consisting of the two archbishops of Dublin, the moderator of the synod of Ulster, and a few other commissioners nominated by the crown. The main feature of difference between this board and the society it superseded, generally called the Kildare Place Society, from the site of its offices and model school, is, that instead of insisting on the Bible being used as a school-book in all cases, selections from it are employed for the purpose of general education, and a portion of every week set apart, in which the clergy of each religious persuasion may instruct the pupils of their own flock in the peculiar tenets of their doctrines. The board has been too short a time in existence to form a decisive opinion as to its probable results. Its views are sufficiently extensive. It proposes to establish five professorships in the training institution: 1. Of the art of teaching and conducting schools; 2. of composition, English literature, history, geography, and political economy; 3. of natural history in all its branches; 4. of mathematics and mathematical science; 5. of mental philosophy, including the elements of logic and rhetoric. Every candidate for the charge of a school is to study at least two years in this department, so as to receive instruction in all the departments of knowledge there taught. It is also proposed to establish a model-school for each county, in which all candidates for admission into the central training establishment should undergo a preparatory process of instruction. The annual salaries of teachers of primary schools is estimated at L.25, with a gratuity of L.5 dependent on good conduct; and that of a teacher in the model schools at L.100, with two assistants at L.50 each.

The population of Ireland being estimated at 8,000,000, of which about one seventh, or 1,140,000, are between the ages of seven and thirteen, and as one half of that number would require the aid of the national system of education, there should be 5000 schools, of an average of 100 pupils each, established. Supposing this number to be completed in nine years, during which the expenses would fluctuate according to the number of schools erected each year, it is estimated that the system could be carried on permanently at an annual expenditure of about L.200,000. The amount is very great, yet probably not more than the magnitude and importance of the undertaking requires. The following table contains a statement of it, formed from the latest official document presented to parliament, and containing also an account of the sums already expended in carrying the plan into effect, during the three years since the issuing of the commission.

Expenditure of the Commissioners of National Education during the time of the existence of the Commission, and an Estimate of the Expenditure required to render it effective in future.

Since the commencement of the present century, four parliamentary inquiries have been instituted relative to this great national subject. The first, which commenced in 1810, published fourteen reports, containing a copious, accurate, and well-digested view of the then state of public education in Ireland, which presented a very discouraging detail of negligence and abuse among those to whom the care of the funds granted for education had been intrusted. The summary of it furnishes the following statement of the number of endowed schools and pupils, and the expense of their education:

Schools.	Annual Income.	No. of Pupils.	Average Cost of each.
Classical	L.9,000	1000	L.9
English	70,000	4200	19

in which latter average the maintenance of the pupils is

Statistics. included in many cases. The total number of pupils in seventeen dioceses out of twenty-two, from which only returns could be obtained, was 3736 schools, containing 162,467 pupils, of whom 45,490 were Protestants and 116,977 Catholics; whence the commissioners inferred that the total numbers of schools and pupils in Ireland were 4600 and 200,000. The second parliamentary inquiry was made during the progress of taking the census in 1821, in which the enumerators were required to report the number of pupils in each school. The result not being a primary object of inquiry, cannot be considered as strictly accurate. In 1824 another parliamentary commission was issued, which published a very minute statement of all the important particulars relative to the numbers, religious persuasions, and localities of the teachers and pupils, and paved the way for the formation of the board of national education, already noticed. The reports of this board form the fourth official statement on the subject. The three last-named sources supply the following summary of the state of education at the periods stated in them, throughout the four provinces of Ireland:

Number of Pupils receiving Public Instruction in the Years specified.

	1821.			1826.				1834.

Antiquities. In a general view of the country, the antiquities cannot be wholly passed unnoticed, although, to do justice to the subject, a much larger scope would be required than the limits here prescribed will permit. They may be classed in two great divisions, Pagan and Christian. Of the former, the round or pillar towers are the most striking and unique. They are tall, narrow, circular buildings, generally from forty to fifty feet in exterior circumference at their base, rising to a height of upwards of a hundred feet, topped, when perfect, with a conical roof, having the entrance several feet above the level of the surrounding country, some of them with projections for four or five tiers of floors, and with four small windows near the summit, generally opposite to the cardinal points. The sites of upwards of ninety of them have been discovered. Their origin and purpose are wrapt in equal uncertainty. That they were anterior to any other erections of stone in the country is now generally admitted; and the opinion that they were somehow connected with the ceremonies of fire-worship is gaining ground. Altars, commonly called Brehon's chairs, circular enclosures of huge pillar stones, rocking stones, cromleachs, and cairns, are to be found in several places; Danish raths or moats everywhere. Among the more anomalous antiquities of this class, a building, called by Vallancey a ship temple, near Dundalk, a subterraneous, cruciform cavern at New Grange, and a singular circular building in Kerry, formed of stone without mortar, of the appearance of an amphitheatre, are the most singular. Weapons and implements of mixed metal, and ornaments of pure gold, found in bogs, may be referred to the same period.

The Christian antiquities may be classed into ecclesiastical, military, and civil. The first comprehend the monasteries, churches, chapels, and cells, of which some are large and of an imposing appearance, though none worthy of comparison in these respects with similar buildings in England or on the Continent, while others are of very limited dimensions and inartificial structure. Of the castles, some retain traces of great feudal grandeur; but the greater number are merely square forts, erected for the reception of a small detachment adequate to guard a pass, or keep a surrounding sept under control. The buildings of a character purely civil are confined to corporate towns.

Conclusion. A retrospect of the preceding concise summaries of Irish history and statistics may serve to show, that though much has been done towards the full development of the capabilities of the country, so as to enable it to contribute its full share to the maintenance, and derive its adequate portion of advantage from the prosperity, of the empire of which it forms so important a part, much still remains to be effected. During the period that has elapsed since the revolution in 1688, a revolution still more pregnant in consequences to Ireland than either to England or Scotland, a variety of tranquillizing remedies have been applied to heal the evils of centuries of turbulence and discord, each of which was in turn deemed a panacea of power to eradicate every grievance. Shortly after that period, education, on principles exclusively Protestant, was expected to secure not only the allegiance, but the conversion, of the great body of the people. Agricultural improvement was then recommended. A closer connection with the other portion of the empire was afterwards suggested. Reform was called for, and now a very prevalent longing indicates itself among the great body of the people for the restitution of its domestic legislature. Education has been tried repeatedly, and in various forms, on a scale of liberal, if not lavish expenditure. Agriculture has extended itself into every part. Religious distinctions have been done away with. Reform has been procured. Yet still a country, endowed beyond most others, through its natural resources, with capabilities for the attainment of wealth, prosperity, and happiness, continues in a state of comparative destitution as regards the means of subsistence, and of degradation as respects the intellectual character of the great mass of its population. A contemplation of this fact has led some to the conclusion that there is something anomalous in the Irish character which prevents the means of melioration, effective elsewhere, from acting beneficially upon it. Such a conclusion would be as disheartening to the philanthropist, who aims at the improvement of the people, as degrading to the nation that merited the imputation. Before it be irrevocably formed, one experiment more should be added to those already tried, founded on the principle that Irishmen are moulded of the same material as the rest of mankind,—the application of a steady, well-devised system of cheap government, and even-handed justice.

IRELAND, New, an island in the eastern seas, north from New Britain. It is long and narrow, and extends from north-west to south-east about 190 miles. Its aspect from the sea is very mountainous, and appears to be covered with thick woods, which abound in pigeons, parrots, and other birds. The inhabitants are in a state of barbarity, black and woolly headed like negroes; but without the flat nose and thick lips. Their canoes are very long and narrow; one of them, that was formed of a single tree, was not less than ninety feet in length. It is situated between Long. 150° 30′ and 153° 5′ E. and Lat. 33° 40′ and 50° S.

IRENÆUS, St, a bishop of Lyons, was born in Greece about the year 120 of our era. He was the disciple of Pappias and Polycarp, by whom, it is said, he was sent into Gaul in 157. He lived at Lyons, where he performed the office of a priest; and in 178 was sent to Rome, where he disputed with Valentinus, and his two disciples Florinus and Blastus. At his return to Lyons, he succeeded Photinus, bishop of that city; and suffered martyrdom in 202, under the reign of Severus. He wrote many books in Greek, but there only remains a barbarous Latin version of his five books against heretics, some Greek fragments in different authors, and Pope Victor's letter mentioned by Eusebius. The best editions of his works are those of Erasmus, in 1526; of Grabe, in 1702; and of Father Massuet, in 1710.

He ought not to be confounded with St Irenæus the deacon, who, in 275, suffered martyrdom in Tuscany, under the reign of Aurelian; nor with St Irenæus, bishop of Sirmich, who suffered martyrdom on the 25th of March 304, during the persecution of Diocletian and Maximianus.

IRENE, empress of the east, celebrated for her valour, wit, and beauty; but detestable for her cruelty, having sacrificed her own son to the ambition of reigning alone. She died in 803.

IRIS, in *Physiology*, the rainbow. The word is Greek, ἶρις, supposed by some to be derived from εἰρω, I speak, I tell; as being a meteor that is supposed to foretell, or rather to declare rain.

Iris is also applied to those changeable colours which sometimes appear in the glasses of telescopes, microscopes, and such like instruments, and is so called from their similitude to a rainbow. The same appellation is also given to that coloured spectrum, which a triangular prismatic glass will project on a wall, when placed at a due angle in the sunbeams.

IRJAH, an Afghan town in the province of Cabul, fifty-five miles S.E. from the city of Cabul. Lat. 33° 54′ N.; Long. 69° 5′ E.

IRKOUTSK, an extensive government of Russia, comprehending all the eastern part of Siberia or Asiatic Russia. It is bounded on the east by the Pacific Ocean, or, more properly, by its gulfs called the Seas of Kamtschatka, Okhotsk, and Anadyr; on the north by the Frozen Ocean; on the west by Tobolsk; and on the south by vast chains of mountains, continued from the Altai chain, by which it is separated from Chinese Tartary. It extends about twenty-eight degrees from east to west, and twenty-five from north to south, and comprises 126,460 square geographical miles. It was erected into a separate government in 1763, being formerly included in the government of Tobolsk; and, in 1783, the Empress Catharine conferred on it the privileges of a state. It was converted into a separate government, owing to the great extent of the country, and the same cause occasioned its subsequent division into four separate districts, namely, Irkoutsk Proper, Nertschink, Yakantsk, and Okhotsk; the first comprehending the southern and fertile districts situated round the Baikal, and near the sources of the Lena and its tributaries. Yakantsk extends as far as the Arctic Ocean, comprehending the vast and frozen plains which extend northward to that sea. Okhotsk extends along the eastern shore of Asia, and includes not only Kamtschatka, but the Aleutian and Kurile isles, thus bordering on one side with America, on the other with Japan. It is traversed by the Lena and its tributaries, throughout its whole extent from north to south. There are also the Olonek, the Indigirka, and the Kovyma, which are large rivers, and fall into the icy sea. An imperfect census has been made of the population, according to which they were reckoned at between 400,000 and 500,000, and they have been considerably increased. Russians and Cossacks form a considerable proportion of the inhabitants. These are composed of colonists, merchants, and of those who are employed in the civil and military establishments of the state, Great part of the province is occupied by the native tribes. who lead a wandering and pastoral life, or gain a living by hunting and fishing. The most numerous of these are the Tunguses. There are also the Mongols, who occupy the southern parts; the Juraki, a Samoiede tribe, who inhabit the northern districts in the Icy Sea; the Yakantes and Koriaks, who dwell on the eastern coast, and derive a very precarious living from pasture and the chase; the Tschutchi, who occupy the north-east point of Asia; and the rude inhabitants of the Aleutian and Kurile islands.

IRKOUTSK, the capital of the above government and district, containing 1500 wooden houses, with two houses of stone. The streets are unpaved, though, owing to the fineness of the weather, they are seldom dirty. It contains thirty-three churches and two cloisters, and is also the seat of an archbishop, and the station of the officers of the government and a considerable body of troops. A seminary is maintained here by government, a popular school, and, since 1762, a school has been established for the Japanese language and navigation. An hospital was also established in 1772 for the small-pox. Irkoutsk is also a commercial mart of considerable importance, and is the residence of many merchants engaged in the trade between Russia and China, which is carried on at Kiachta. It has in a good degree the aspect of a Chinese town, from the quantities of porcelain, enamelled and lacquered ware, and Chinese articles of dress and furniture, with which the houses are filled. Long. 103° 30′ E.; Lat. 52° 16′ N.

IRON, one of the metals, and one of the hardest and most useful, as well as the most abundant.

IRON-MAKING.

I.—HISTORY.

History.

It is probable that iron was first accidentally obtained during the operation of carbonizing wood. If the surface of the country where this process was performed abounded in ores of iron, fragments might casually find admission to the fire, and, sinking through the ignited charcoal, become partially reduced. An analogous case is presented to us in the roasting of ironstone as now practised; some peculiar species of which, associated with a large quantity of bituminous matter, have, under favourable circumstances, produced, during that process, plates of imperfectly malleable iron.

Once discovered, whether by accident or otherwise, it is scarcely conceivable, that a metal possessed of so many valuable and obvious properties, would be long suffered to remain an unique specimen. The benefit likely to accrue, by being able to procure it at will, would lead at once to numerous experiments, probably at first attended with little success. The simple, turf-covered fire of charcoal, in which the discovery was made, being found inadequate to the regular attainment of the desired end, would give place to the rude structure of stone, and this, subject to various and gradual improvements during a long period of years, would at length be superseded by the powerful blast-furnace such as we find it at the present day.

To trace the causes and principles of these improvements, the manner in which they modified the original process, and to shew their influence on the extent and progress of the iron trade from its commencement, cannot be uninteresting. The first smelting-furnace peculiar to the manufacture, was undoubtedly the air-bloomery, a low conical structure, with small openings at the bottom for the admission of air, and a larger orifice at top, for carrying off the gaseous products of combustion. In order to produce iron, the interior was filled with alternate strata of charcoal and ore; fire was applied at the lowest part, and the heat was regulated by the narrowing or enlarging of the small apertures. Such a structure it probably was that the Romans made use of to smelt the ores of this island; scoria, the refuse of ancient bloomeries, occurs in various localities, in some cases more particularly identified with that people, by the coincident remains of altars inscribed to the god who presided over iron. Park represents the rude furnace just described as employed by the Africans; indeed, with some slight modifications, it is still retained even in Spain, and along the coasts of the Mediterranean, where rich specular ores are worked.

At what time the simple air-bloomery ceased to be the iron-making furnace of this country, it is impossible to say, the event being so remote. It is certain, however, that the next era which marked the progress of the manufacture was occasioned by the introduction of bellows, a very obvious substitute for the natural current of air hitherto employed. This instrument, which had probably arrived at some degree of perfection before its application to the new purpose, presented at once considerable advantages. It obviated the necessity of an elevated site for the bloomery, and it put the blast more immediately under the dominion of the smelter, which before had been irregular or intermittent during the progress of the same process, and at all times more or less dependent on the weather. By the application of bellows, some slight alterations in the furnace were rendered necessary. The new construction was built of stone, capable of enduring a high temperature, about two feet in height, and from one and a half to two feet square within. Besides the orifice or chimney at top, there were two openings, one large in front, for drawing out the metal, the other of smaller dimensions behind, for the insertion of the bellows pipe. Such was the *blast-bloomery*.

History.

Let us now contrast the operation, with its products in each case, as performed in the two furnaces which have been described, and which differ apparently so little. In the *air-bloomery*, the principle of reduction consisted in the deoxidation of a very rich ore, which, broken into moderately-sized pieces, was subjected to a long-continued cementation. The ore was, of course, never brought into a fluid state, although the fragments became soft, and tended to coalesce. A small quantity of the associated earthy matter was separated in the furnace. Accordingly, when taken out, the iron was imperfectly malleable, being mixed, to a greater or less extent, with scoria and unreduced oxide. This put at once under the hammer of the smith, was fashioned into a rude bloom, and, with other hammerings, the greater portion of extraneous ingredients was removed. In the *blast-bloomery*, on the other hand, although the furnace was probably charged in the same manner, and although the fire was still urged by common air, yet, on account of the greater strength and regularity of blast, and consequently greater heat produced, the result was very different. The ore, after being deoxygenated, imbibed a portion of carbon, and sunk in a fluid state to the bottom of the furnace. Thus the resulting metal was not, as with the *air-bloomery*, malleable; it was rather a species of steel, utterly useless to the workmen of these days, unless we imagine that a sort of refining process had been invented. Here, then, it seems necessary to infer, that the fluid metal was covered afresh with charcoal, the slag or vitrid matter having been previously run off; and that the nozzle of the bellows-pipe being inclined, a continued stream of air was made to play upon the surface. In this manner the carbon was burned out, the metal worked thick and tough, and fresh surfaces being continually exposed, became eventually capable of extension under the hammer.

To form an accurate idea of what the iron trade must have been during the period that the blast-bloomery was the exclusive instrument of manufacture, is not permitted to us, by the existence of any authentic document. Some conjecture, however, favourable to the opinion of its extreme insignificance, may be advanced, when we call to recollection the diminutive size of the furnace, the small quantity of iron extracted from the ore (about one-half of what it contained), and the inconsiderable extent to which, at so early a stage of society, the division of labour had been carried. This, however, was a state of things which every day improved. To the progress of internal communication, then in its infancy, the appreciation and pursuit of new sources of wealth, the establishment of manufactures, and to various other causes, as continually favouring the rapid consumption of iron, are to be attributed those improvements in the bloomery, which finally led to the construction of the blast-furnace, with all the innovations on old-established practice, which its gradual introduction as naturally produced.

It is reasonable to suppose, that an increasing demand led the iron-smelter to speculate on the facilities which would be given to his trade, by enlarging the capacity of the bloomery. This, however, he probably did not foresee; namely, that every such enlargement, by prolonging the descent of the ore through the furnace, exposed it to a lengthened contact with the charcoal, and consequently to a proportionally great absorption of carbon, and that thus eventually the different varieties of cast-iron, a compound till then perhaps unknown, would be produced.

From the time that cast-iron became the product of the smelting-furnace may be dated the refining of iron, considered as a separate operation, and requiring as such a separate furnace and machinery. Enlargements in the blast-bloomery, unaccompanied by any alteration in form, could not be so made beyond a certain limit. After the furnace had reached a certain height, the column of materials in the interior would be found to weigh so heavily downwards, as to repress the ascent, and render soft the quantity of blast, which had been sufficient to penetrate a column of three or four feet in the old bloomery. It was then that a suspending agent was first thought of, and those internal buttresses were introduced, which either then or subsequently received the name of boshes. These, by creating immediately above the tuyeres a lateral suspension of the materials, relieved the pressure on the central parts of the furnace, and allowed the blast to ascend with comparative freedom. Whilst the good quality of the iron and the regularity of the process were thus insured, increase in quantity was the result of improvements in the blowing apparatus, which, hitherto worked solely by animal power, was now made to depend on the greater efficiency afforded by the employment of water. With these modifications, the furnace, as regards construction, was essentially the same as that at present used, though not so large; indeed, until the introduction of coke at a much later period, the blast-furnace seldom exceeded fifteen feet in height, by six at the widest diameter. During the long period that the air and blast-bloomeries had been the only iron-making furnaces, large accumulations of scoria, containing from 30 to 40 per cent. of iron, had formed. The more perfect operation of the blast-furnace allowed these to be re-smelted with great advantage; a new species of property was thus created; extensive proprietorships of Danish and Roman cinders were formed; large deposits of scoria, which for ages had lain concealed beneath forests of decayed oak, were dug up; and in Dean Forest, it is computed that twenty furnaces, for a period of upwards of three hundred years, were supplied chiefly with the bloomery cinders, as a substitute for iron-ore.

At what period the complete transformation of the blast-bloomery into the blast-furnace was effected, it is impossible to say. It was probably during the early part of the sixteenth century, as we find that in the seventeenth the art of casting in metal had arrived at a great degree of perfection; and in the reign of Elizabeth there was a considerable export trade of cast-iron ordnance to the Continent.

In the forest of Dean are the remains of two blast-furnaces, which formerly belonged to the kings of England. But since the commencement of the struggle between Charles the First and his Parliament, these furnaces have not been in blast. Calculating from the quantity of scoria accumulated in the neighbourhood, and which appears to have lain undisturbed for the last two centuries, Mr Mushett[1] has attempted to deduce the period of their erection, which he conceives to have been about the year 1550, in the time of Edward the Sixth.

In reverting to the different facts which have been stated, there is one thing which immediately suggests itself to the imagination, namely, the influence which the gradual adoption of improvements must have exerted in changing the site and locality of the manufacture. The air-bloomery, as has been before noticed, was almost invariably placed on elevated ground. At the introduction of bellows, the furnace became, to a certain extent, independent of the causes which till then had determined its site, and was removed to a lower level, more convenient, as being in the immediate neighbourhood of the ironstone, or of the hamlet where the workmen resided. Finally, the necessity of a more perfect blast than could be obtained by mere animal power, again changed the seat of manufacture, which now sought the deeper valleys, where the drainage of the surrounding country realized a powerful fall of water. In all that has hitherto been said, wood charcoal has been understood as supplying the requisite material for every operation. But the wants of a constantly increasing population, not less than the great consumption of the iron-furnaces themselves, at length gave a check to the manufacture, by depriving it of its vital support, the essential supply of fuel. In many counties, wood had been destroyed to such an extent, that the cutting down of timber for the use of the ironworks was prohibited by special enactments. The forests of Sussex alone appear to have been exempted from this general decree of conservation.

A languishing period of manufacture accompanied the falling off in the supply of charcoal, the number of furnaces decreasing three-fourths; so that, in 1740, the amount of iron produced, which but a short time before is said to have been 180,000 tons a year, was only 17,350 tons. The counties which produced the iron, with the number of furnaces to each, were as follow:

	Furnaces.	Tons.
Brecon,	2	600
Glamorgan,	2	400
Carmarthen,	1	100
Cheshire,	3	1,700
Denbigh,	2	550
Gloucester,	6	2,850
Hereford,	3	1,350
Hampshire,	1	200
Kent,	4	400
Monmouth,	2	900
Nottingham,	1	200
Salop,	6	2,000
Stafford,	2	1,000
Worcester,	2	700
Sussex,	10	1,400
Warwick,	2	700
York,	6	1,400
Derby,	4	800
	59	17,350

	Tons.	Cwt.	Qr.
Annual average quantity for each furnace,	294	1	1
Weekly do. do.	5	13	0

James the First granted patents to ironmasters in different parts of the kingdom for using pit-coal in the manufacture of iron; many obstacles, however, arose in the way of this improvement. The denser substance and incombustibility of coke, and the less active affinity of its carbon as compared with charcoal, for iron and oxygen, required not only a more copious and powerful injection of air, but also that the iron-making materials should remain a longer time together in the interior of the furnace than had hitherto been necessary. An ignorance of the causes of failure herein implied, operated long and seriously; but all difficulties were at length surmounted by enlarging the height of the blast-furnace, so as to prolong the descent and contact of the ore and coke, and more especially by the eventual application of the steam-engine, which rendered the working of the blowing machinery at once regular and powerful.

[1] See *Philosophical Magazine* for 1822.

History.

It was now that furnaces arose, having a capacity of three, four, five, or six thousand cubic feet; whilst of late years, furnaces of ten or twelve thousand cubic feet have been erected, without the maximum effect being decidedly obtained. By the collation of the following table with that which was given as representing the state of the manufacture in 1740, it will be seen that, in 1788, although the absolute quantity of charcoal pig-iron produced was less by 4250 tons, that considerable improvements in the process must have been made, as indicated by the great increase in the amount of produce to each individual furnace.

Counties.	Furnaces.	Tons each.	Total.
Gloucester,	4	650	2,600
Monmouth,	3	700	2,100
Glamorgan,	3	600	1,800
Carmarthen,	1	400	400
Merioneth,	1	400	400
Shropshire,	3	600	1,800
Derby,	1	300	300
York,	1	600	600
Westmoreland,	1	400	400
Cumberland,	1	300	300
Lancashire,	3	700	2,100
Sussex,	2	150	300
	24	Making,	13,100

	Tons.	Cwt.	Qrs.
Annual average produce from each furnace,	545	16	2
Do. of the former period (1740),	294	1	1
Annual increased produce in favour of the improved period,	251	15	1
Average weekly quantity produced in 1788,	10	9	3
Ditto 1740,	5	3	0
Weekly increase in favour of the improved period,	4	16	3

At the same period the number of coke blast-furnaces, with the quantity of iron produced in each county, were as below:

	Furnaces.	Tons each.	Total.
Shropshire,	21	1,100	23,100
Stafford,	6	750	4,500
Cheshire,	1	600	600
Derby,	7	600	4,200
York,	6	750	4,500
Cumberland,	1	700	700
Glamorgan,	6	1,100	6,600
Stafford (about to blow),	3	800	2,400
Brecon,	2	800	1,600
	53		48,200

	Tons.	Cwt.
Annual average produce,	907	0
Weekly do. do.	17	9

Annual manufacture at same period of charcoal iron, 13,100

In the same year there were erected and blowing in Scotland the following furnaces:

	Furnaces.	Tons.	Total.
Goatfield,	1	700	
Bunawe,	1	700	1,400
Coke furnaces.			
Carron,	4	1,000	4,000
Wilsontown,	2	800	1,600

In Britain, total quantity in 1788,	68,300
Ditto in 1740,	17,350
Annual increase of pig-iron,	50,950

About the year 1796 it was contemplated by Mr Pitt, to add to the revenue by a tax upon coal. This, of course, led to a powerful opposition on the part of the manufacturing consumers, particularly in the iron trade. A committee was appointed, witnesses were examined, and the measure was abandoned as unwise and impracticable. The following table exhibits an abstract of the facts collected, and shews the rapid progress of the iron trade in the course of the eight preceding years:

Counties.	No. of Furnaces.	Excise Return of Iron Made.	Supposed Quantity by the Trade.	Actual Return.
Chester.......	2	4,710	2,200	1,958½
Cumberland..	4	5,144	3,000	2,034
Derby.........	3	2,138	2,138	2,107
Gloucester....	2	380	380	380
Hereford......	5	2,850	2,850	2,529
York..........	22	21,984	21,987	17,947

Sussex........	1	172¾	173	173
	104	167,321¾	133,950	108,793

	Tons.
The return from Scotland exhibited a list of seventeen furnaces, and an exact return of pig-iron manufactured,	16,086
Making a whole annual quantity of	124,879
Annual average produce from each furnace, including the charcoal furnaces,	1,032
Annual average of 1788, including the charcoal furnaces,	800
Increase in tons,	232

As a proof of the rapid strides and progress which the trade was now making, it may be added, that, in the six following years, there were building in England and Wales, forty additional furnaces, and in Scotland seven; the collective manufacture of which was computed at upwards of 170,000 tons annually.

From the preceding statements, some interesting information may be elicited with regard to the extent of the manufacture of iron, at different periods, in various parts of the kingdom, where it is either still successfully prosecuted, or become altogether extinct as a branch of trade.

In the year 1740, the date of the earliest document in our possession with regard to the distribution of blast-furnaces, we find that Gloucester produced a much greater quantity of iron than any other county in Britain. There the manufacture was well understood; indeed, it had been carried on in the forest of Dean from the earliest period. The furnaces were large, as compared with those of other districts; and, in consequence, the amount of iron to each furnace exceeded the general average.

At the period to which we refer, Sussex contained the greatest number of furnaces. With a few in Kent, the residue required to make up the annual complement of iron, at that time about 17,000 tons, were scattered sparingly throughout the midland counties, and along the Welsh borders. Eight-and-forty years afterwards, a little subsequent to the introduction of coke in smelting, the coal counties began to assume that rank in connection with iron, which for ages had been more particularly accorded to the woodland districts; and we find Shropshire making rapid strides towards that importance as an iron-making county, which, in conjunction with Staffordshire, it has ever since maintained. In Shropshire, there was then made a proportion of charcoal iron little less than the produce in that article of Gloucester, Monmouth, or Lancashire, whilst the quantity of coke pig-iron which it turned out, amounted to the enormous sum (comparatively speaking) of 23,100 tons; thus equalling the collective manufacture of all the other coke pig-iron districts in Britain. In the year 1796, the iron manufacture had become well-nigh extinct in Sussex, and altogether so in Kent. On the other hand, South Wales had made great progress towards pre-eminence, though still exceeded by the Shropshire and Staffordshire iron-works. These latter counties, indeed, containing within themselves the seats of the most extensive manufactories of small iron articles, have always required, for their own supply and consumption, an incredible quantity of that material. For a long time, also, the Staffordshire iron-masters enjoyed almost exclusively the advantages conferred by the rolling-mill in the production of various descriptions of iron, such as nail-rods, boiler-plates, hoop and sheet-iron, wire, &c. These advantages they still enjoy to a certain extent, and, in consequence, maintain a greater price for their iron than the Welsh iron-masters. It is in Staffordshire and Shropshire that the manufacture of iron is seen in its greatest perfection. The beauty and finish of their small rolling machinery, which is run at an immense speed, enabling them to secure almost the whole of the very small and extra sizes of iron, which they throw off at little more cost than the Welsh manufacturers do their common bars. It is in South Wales that the furnaces and manufactories produce the greatest quantity; in Shropshire and Staffordshire that the highest excellence in rolling has been attained.

In 1806, a bill was brought into parliament by Lord Henry Petty, having for its object a tax of L. 2 per ton on all pig-iron made. This measure, which exhibited throughout a remarkable ignorance of the nature and minutiæ of the iron trade, excited at once a determined opposition, and was at length abandoned. Had it been carried into effect, the price of all kinds of ironmongery would have risen to an enormous extent; as will be obvious, from the following statement in reference to common nails. At that period, ten tons of pig-iron were required to make five tons of nails; shewing, in the various processes of puddling, rolling, slitting, forging, &c. a loss of precisely one-half the material. Thus, with intermediate expenses, the proposed tax of L. 2 would have advanced nail-rods at least per ton L. 4, 10s. Six tons of nail-rods would therefore have cost the nail-ironmonger more than he was then paying, about L. 27, which, divided upon five tons of nails, is L. 5, 8s. per ton; and this laid out by the retail dealer, would have caused an additional charge of, let us say, 12s, making in all, on nails, L. 6. per ton.

This statement, which is made from one drawn up at the time, is of course not altogether applicable in the present improved state of the iron manufacture. It affords, however, a very correct exposition of what the general consequences would have been, had the tax been imposed. During the time that the project was in agitation, a great many important facts were elicited; amongst others, the annual amount of pig-iron made in the country was shewn to be at least 250,000 tons.

Since then, the manufacture has gone on increasing, although subject to great depression in 1816. For a considerable time previous to the general peace which ensued in that year, the British and mercantile navies had been continually requiring immense quantities of manufactured goods, and the sudden cessation of large orders and contracts, of course, threw a damp over the iron trade.

In 1820, it was computed that the annual manufacture of pig-iron was,

	Tons
In Wales,	150,000
Shropshire and Staffordshire,	180,000
Yorkshire and Derbyshire,	50,000
Scotland and other places,	20,000
Total,	400,000

In 1827, the make had increased by 290,500 tons, as shewn below:

	Furnaces.	Produce in Tons.
South Wales,	90	272,000
Staffordshire,	95	216,000
Shropshire,	31	78,000
Yorkshire,	24	43,000
Scotland,	18	36,000
North Wales,	12	24,000
Derbyshire,	14	20,500
Total,		690,500

of which three-tenths are supposed to have been foundry-iron. From this statement, it appears that the Welsh works are considerably more productive than those of any other district; a fact to be in part attributed to their comparatively great size.

Within these last few years, the produce of iron in Wales has greatly increased. The quantity sent down the Glamorganshire canal to Cardiff for exportation, chiefly manufactured in the immediate neighbourhood of Merthyr Tydvil in 1828, was 85,714 tons. At the same time, the shipments from the town of Newport amounted to 108,000 tons. In 1830, the iron exported was less from both places by 2000 tons; indeed the collective manufacture of this year was not more than in 1827, three years before. In 1833, the quantity exported from Cardiff was 112,315 tons, exceeding the exportation of 1828 by upwards of 26,000 tons; whilst, at the same time, the customhouse books at Newport exhibited a corresponding increase. In the year 1834, Cardiff exported 110,797 tons; of this quantity 68,420 tons were the manufacture of two works alone.

In glancing at the different iron and coalfields of Britain, it is matter of astonishment that Northumberland and Durham, possessing within themselves all the requisites for the iron manufacture, should yet be so far behind, compared with other much less favoured districts. The only way of accounting for this apparent apathy to extensive mineral treasure, is the fact, that the attention of capitalists in that part of the country has hitherto been exclusively devoted to the working and exportation of the coal alone.

Of late years, Scotland has made considerable progress in the iron manufacture. The opening out of the numerous railways through the immense coalfield in the neighbourhood of Glasgow, has brought to light strata of the richest ironstone, with coal of the most suitable quality for the manufacture of iron. A stimulus has consequently been given to the trade, which, with the general adoption of the hot-air process, promises to raise Glasgow into importance as an iron district. No town, in fact, possesses greater facilities for the sale of its produce, commanding, as it does, the east coast, London, and Liverpool markets, at two-thirds the cost of freight from either Wales or Staffordshire, and also a ready outlet to the Atlantic.

In 1835, a return was made to an order of the House of Commons, moved for by Mr Guest, containing an account of the quantities of iron imported into, and exported from, the United Kingdom in the years 1833 and 1834; also an account of the quantity of British iron, including unwrought steel, exported in the same years. From this document it would appear, that in 1833 there were 17,913 tons of bar-iron imported into this country from Russia, Sweden, and other places. In the year 1834, the quantity

History.

imported was 16,215 tons, shewing a decrease in the importation of the preceding year, to the amount of 1698 tons; the exportation of this description of iron in 1833 being 2024 tons, and that of 1834 being 2885 tons. The account shews an increase of exportation in 1834, as compared with the previous year, of 861 tons. By the second account it appears, that the quantity of British iron, of all descriptions, exported in the year 1833, was 160,226 tons (exclusive of 1587 tons of unwrought steel), and the quantity exported in the year 1834, being 156,456 tons (exclusive of 1709 tons of unwrought steel), there is a decrease in the quantity of British iron exported in 1834, as compared with the preceding year, to the amount of 3770 tons. This falling off in the quantity of iron exported, is to be attributed, in great part, to the difference which took place in the United States with the President and the Bank, in consequence of which, large orders for iron sent here were withdrawn. The demand for that country is now larger than ever, and continues to increase, in addition to which, the numerous railways in progress in this and other countries, have given such an impulse to the trade, that in October 1835, No. 2. iron at Cardiff was quoted at L. 7 per ton. As in some measure connected with the subject under consideration, it may be added, that in 1833, 16,497 tons of hardwares and cutlery, of the declared value of L. 1,466,361, were exported from the United Kingdom; and that in 1834, 16,275 tons of the same of the declared value of L.1,485,233 were exported, shewing a decrease in the exportation of the year 1834, as compared with 1833, of 222 tons, whilst, at the same time, there is an increase on the value to the amount of L. 18,972.

Since the introduction of the blast furnace in its present form, many improvements have been made in the various processes of the manufacture, but none of such importance as the rolling-mill and puddling-furnace, these enabling the manufacturer to increase his quantity of finished iron at will, always having a stock of pigs on hand to meet the demand of the market. Previously to the introduction of puddling and rolling (by Mr Cort in 1785), so inadequate was this country to the supply of its own demands, that it imported from Russia and Sweden, the enormous quantity of 70,000 tons of bar-iron annually, being upwards of 40,000 tons more than the importation of 1834. For several years past, numerous patents have been taken out in connexion with iron-making, bearing upon various parts of the manufacture; for instance, the application of the spare-heat from the furnaces to the roasting of ore; the use of carburetted hydrogen in smelting; the introduction of forge and refinery cinder in the blast and puddling furnaces; the use of salts of soda and potash, to shorten the process in the latter, and bring the iron, as the workmen term it, "sooner to nature." But none of the improvements here aimed at, are likely to be attended with any thing like the advantages which arise to the country from the application of heated air in smelting. This invaluable process, the invention of Mr Neilson of Glasgow, will be described in an after part of this article. It has already been adopted with immense advantage in Scotland, France, Russia, and in several of the English and Welsh iron-making counties.

The following list of prices of bar-iron, shews the fluctuations in value undergone by that article during the last twelve years:

List of Prices.

1835,	5	10	0	...	7	0	0

The superiority of bar-iron, manufactured solely from mine, without admixture of cinder, is so well established, that an extra charge is usually made for it of from 10s. to 15s. per ton at the work. The workmen are generally paid a fixed price per ton on all iron made, a ton weighing 20 cwt. of 120 lb. each. The manufacturer sells it out per ton of 20 cwt. of 112 lb. each, making an allowance to the buyer of 8 lb. per ton, which is denominated drafts. This allowance is now done away with, agreeably to the 4th and 5th of William III. cap. 49; a ton of iron is therefore now only 20 cwt. of 112 lb. to each.

Manufacture.

II.—THE MANUFACTURE.

The manufacture of iron may be considered under two divisions; the one comprising all those particulars which relate to the production of crude or pig-iron in the blast-furnace; the other, a detail of the operations at the forge and rolling-mill, whereby the pig-iron is rendered malleable, and brought into a state fit for the manufacturing consumer.

The blast-furnace as generally used throughout this country, is a large mass of masonry, most frequently square, though sometimes round at the base, from which the walls are carried up slightly inclined to the vertical, thus forming externally a truncated pyramid or cone. At each side is a large arched opening, so placed for the more convenient insertion of blast-pipes, and for running out the melted metal. At the top is the tunnel-head, a cylindrical erection of brick-work, having one or more doors, through which the furnace is charged with the materials to be smelted. In front of the furnace a roof projects from the wall, beneath which is a bridge or cast-house, where the metal, being run into moulds of sand, forms pigs.

Plate CCCIX. fig. 1. is a section of a blast-furnace, in which the space marked A represents the hearth; CB the boshes, which in principle have been already explained; D the body of the furnace; E the tunnel-head with charging doors of iron; F F F the blast-pipes, entering just beneath the boshes, through small spaces in the brickwork, called tuyeres. Fig. 2. is a ground-plan corresponding with the above section. The greater part of the interior of the furnace is lined with fire-brick, between which and the masonry, a thin stratum or packing of sand is laid. In Wales the materials employed in the construction of the hearth and boshes, is a very infusible plumpudding-stone or quartz conglomerate, large detached blocks of which occur on the mountains, and are familiarly known amongst the workmen by the name of Noah stones. A species of coarse sandstone, belonging to the coal formation, and exceedingly refractory in the fire, is also advantageously used. Slight variations from the form of furnace here given, are of course to be met with; a point of much importance is the proper inclination of the boshes, so that the materials whilst smelting, may neither press too heavily downwards, nor yet be so much retarded, as to adhere in a half-liquid state to the brickwork, and cool there; thus forming what are known by the name of scaffolds, the removal of which is a source of great inconvenience. No general standard for the size of blast-furnaces can be given, as they vary in this respect in almost every iron-making district of Britain. The largest furnaces are those of Wales and Monmouthshire, some of which are upwards of sixty feet in height. In Staffordshire and Scotland, they are generally much less, and from thirty to forty feet in height, by about twelve or fourteen at the boshes, or widest interior diameter, may be stated as a very fair average size. Before leaving this part of the subject, it must be premised that of late years, the cupola-furnace has come extensively into use. Its characteristic feature is general slightness of structure, as compared with the more massive blast-furnace. The walls are circular, built of fire-bricks, and, excepting about twelve or fourteen feet of masonry at the bottom, in no part more than a single course in thickness; the whole, however, are strongly bound together at the joints with wrought-iron hoops, whilst pillars of cast-iron, bolted at each end to embedded rings of the same metal, rise through the foundation to the summit of the tuyere arches, giving considerable firmness and solidity to the structure. Objections have been made to the thin sides of the cupola, as permitting a great loss of heat; these, however, do not seem to have prevented its very general adoption. Cheapness and facility of construction are much in its favour, and a furnace of this kind, when blown with hot air, may certainly be used with great advantage. A cupola twenty feet high, six feet at the boshes, and three feet at top, requiring a blowing-engine of five or six horse-power, can be run up in a week, and may have iron manufactured in it the next. Plate CCCXVII. contains a section and ground-plan of a cupola furnace lately erected at an iron-work in Glamorganshire.

The communication between the ground and the tunnel head is effected in various ways. The Welsh furnaces are invariably placed on the slope of a steep declivity, which affords ready means of access. Where this convenience does not present itself, a small self-acting incline is substituted, or an apparatus is affixed to the engine by which the workmen and smelting materials are carried up and down as may be required. Attached to every iron-work is a steam-engine (or water-wheel), whose sole office is to throw a continued current of air into the furnaces. This is in most cases accomplished simply by attaching to the unoccupied extremity of the beam a piston, which is made to work in a cylinder of large diameter. At every stroke the air, entering this cylinder through proper valves in the covers, is forced into pipes inserted at top and bottom, which convey it to a large spherical vessel, built of boiler plate, whence its own elasticity causes it to flow in an equable and unintermitting stream into the furnace. Plate CCCX. shews the plan, elevation, and section of a blast-engine erected at the Wylam Ironworks, Northumberland, by the Messrs Hawthorn of Newcastle. This machine differs in many respects from the common construction, for a figure of which, in connexion with the blast furnace, see Plate CCCX. AA represent the pillar on which the engine is fixed, BB the blast-cylinder, *c c* the wind-boxes, in which are fixed the discharging valves, *d d* the blast-pipe leading to the furnaces, EE the steam-cylinder, *ff* the force-pumps, *g g* the hand or working-gear, *h h* the cross-heads, *i i i i* the slides for guiding the piston-rods, *k k* the banging-boxes.

The pressure at which the blast enters the tuyeres is from $2\frac{1}{2}$ to $3\frac{1}{2}$ lb. on the square inch of course depending on the area of the blowing cylinder, and the pressure at which the engine is working.

At the Dowlais Ironworks, South Wales, is a blowing-cylinder 12 feet in diameter, with 9 feet stroke, and worked by engines of 260 horse power. By this machine ten or twelve furnaces can be blown.

The diameter of the blast-pipes at the tuyeres is regulated by their number. Where three tuyeres are used, and the pressure is about three pounds, the diameter should not exceed $3\frac{1}{2}$ or $3\frac{3}{4}$ inches. In practice, it is necessary to be very particular with regard to this point, the well-working of a furnace depending much on the attention which is given to the blast. The best quality of cast-iron is produced by a comparatively moderate quantity of air. On the contrary, a strong and powerful blast tends to the production of a large quantity of metal, inferior in every respect, and unfit for the purposes of the foundry.

Behind the furnace, and, if possible, on a level with the tunnel-head, are placed a number of small kilns or ovens for roasting the ore. The ironstone used in the blast-furnaces of this country is a carbonate of protoxide, or more simply a carbonate of iron, in conjunction with different earths, such as alumina, silica, lime, &c. The object in roasting is to drive off the carbonic acid, water, and sulphur. The stone loses in the operation from thirty-five to forty per cent., at the same time becoming partially peroxidized. To produce iron from an ore like this, it is requisite not only that a deoxidating agent should be used, but also that there should be some other substance, such as limestone, to act as a flux, and disengage the earthy from the metalliferous particles, leaving the latter free to the carbonizing influence of the coke. The materials, then, mine or ironstone, coke, and limestone, broken into small pieces, and weighed out in the proportions which have been determined by experience to be the right ones, are introduced into the furnace by the filler, who stands at the tunnel-head, and whose duty it is to see that these proportions be observed, and that the mine and coke are properly burned. He also takes account of the number of charges required to keep the furnace full during the time of his management (twelve hours to the day); and according to this the furnace is said to drive fast or slow. The charge, or quantity introduced into the furnace at once, is a barrowful of coke, containing about twenty cubic feet, with the requisite proportions of mine and flux. These of course differ slightly at different works, according to the quality of the ore and limestone; but it is the general practice to mix rich and poor ironstones together, and thus to bring the latter material as near as possible to some approved standard, containing, say from thirty-five to forty per cent. of iron.

The general action that takes place in the blast-furnace is this: The contents being raised to an intense heat by the combustion of the coke, are brought into a softened state; the limestone parts with its carbonic acid, and, combining with the earthy ingredients of the ironstone, forms with them a liquid slag or scoria; whilst the separated metallic particles, descending slowly through the furnace, imbibe in their passage a large quantity of carbon, pass the blast without oxidation, and, in virtue of superior gravity, settle in the hearth or lowest part of the furnace, from whence, at stated intervals, the fusion is removed in the state of liquid cast-iron. The slag which floats upon the surface of the metal, whilst accumulating in the furnace, is kept constantly running off by an aperture level with the top of the hearth; and it affords well-known indications, by its degree of heat, fluidity, and colour, of the manner in which the materials in the interior are performing the parts assigned them in the operation. Thus, if the cinder has a light greyish colour, or is nearly transparent, and flows freely from the furnace, unsullied by any of the various tints of blue, yellow, and green, afforded by oxide of iron in combination with different proportions of earthy matter, a favourable state of the furnace is indicated. If, from the charge affording such results, a portion of coke be abstracted, or if to it, which is the same thing, a portion of mine be added, the cinder immediately assumes a deep brown or black colour, and flows in a broad, hot, and rugged stream, shewing that the quantity of coke is insufficient to deoxidate the whole of the iron, and that a portion of it, consequently, to the great detriment of the furnace yield, is combining in its state of oxide with the slag, to which it communicates so deep a hue.

With regard to the constitution of blast-furnace scoriæ,

Manufacture.

they are in general compounds of earths and earthy salts, where silica acts the part of an acid, and lime, alumina, magnesia, oxide of iron, &c. are bases. Minerals are thus formed artificially, presenting the most perfect crystalline arrangement, and similar in every respect to some native silicates. Indeed, without mentioning the graphyte or kish which scales from the surface of newly-cast foundry pigs, the splendent copper-coloured cubes of metallic titanium so abundant in breaking up old furnace-hearths, or the dark blue crystallized metallic-looking compound of sand and oxide of iron, the slag from the bar-iron heating furnace, the rejected products of the iron manufacture present perhaps more features of interest to the mineralogist than the residua of any other chemical operation.

During the process of smelting, the interior of the furnace requires to be very carefully watched. The stream of cold air that is constantly rushing through the tuyeres exerts a chilling agency on the melted matter, directly opposed to it, at its entrance. The consequence of this is, the formation of rude perforated cones of indurated scoria, stretching from either side horizontally into the furnace, each one having its base directly over the embouchure of a blast-pipe.

When these project only to a certain extent, they are favourable to the working of the furnace, as the blast is thrown right into the centre, and prevented from flowing up the sides and burning the brick-work.

Sometimes, however, when the furnace is driving cold and slow, these conduits of slag become so strong, and jut out so far as to meet at length in the middle, and thus cause a great obstruction to the entrance and ascension of the blast. When this happens, there is no remedy but to increase the burden, that is, to add more than the usual proportion of mine to the charge; this causes an intense heat, the furnace is said to work hot, and the tuyeres of slag drop clean off from the sides. But this is followed by bad as well as by good consequences; the brick-work is frequently melted, and for a time the iron produced is small in quantity, and of the worst quality.

To bring the furnace again into its proper state, it is now necessary to reduce the burden; the sides, in consequence, become gradually cool, new tuyeres are formed, and the iron produced is good.

At the end of every twelve hours, more or less, the furnace is tapped, that is to say, the aperture in the damstone, which, at the commencement, had been stopped up with a mixture of loam and sand, is re-opened, and the metal, the contents of the hearth, allowed to flow out into moulds made in the sand, of which the cast-house floor consists, thus forming a cast or sow of pigs. When this operation ceases, the damstone is again secured, and the work proceeds as before. In this manner a furnace is kept continually going, night and day, and never ceases to work until repairs are necessary. Incessant action has even been thought essential to the successful carrying on of an ironwork; but the example of perhaps the largest iron-master in South Wales has shewn, contrary to general practice in that district, that smelting may be discontinued for at least one day in the week without any very serious derangement of operations.

At Merthyr, in Glamorganshire, the yield, or quantity of materials required to make a ton of pig-iron, is as follows: 55 cwt. of roasted mine, 25 cwt. of limestone, and $2\frac{3}{4}$ tons of coal. The charge, or quantity of materials introduced into the furnace at once, is 7 cwt. 2 qrs. of roasted mine, one barrow of coke containing about twenty cubic feet, with 3 cwt. 1 qr. 15 lb. of limestone. In all cases, the regular rule is to fill in the coke first, then the flux, and lastly the mine or ironstone. In the Glasgow district, the charge is $4\frac{1}{2}$ cwt. of coke, 3 cwt. of ironstone, 1 cwt. 7 lb. of limestone; total, 8 cwt. 2 qrs. 7 lb. In a furnace twelve feet at the boshes, fifty of these charges, in twelve hours, produce $4\frac{1}{2}$ tons of iron; the same proportions have been known to produce as much as $5\frac{1}{2}$ tons, and as little as $3\frac{1}{2}$. Again, the iron is not always of the same quality; thus exemplifying different states of the furnace, blast, management, &c. In three successive casts of a furnace, in which the amount of charges was, in each case, coke, 11 tons 5 cwt.; ironstone, 7 tons 10 cwt.; limestone, 2 tons 13 cwt.:

The first cast produced	4 tons	10 cwt.	of No. 1. iron,	
second do.	4 ...	12 ...	No. 2. do.	
third do.	3 ...	16 ...	No. 3. do.	

Two different qualities of cast-iron are frequently the product of the same cast. The best kind runs first from the hearth; and the pigs are distinguished from each other by the striæ or furrows formed on their surfaces in cooling, No. 1. preserving a smoother surface than No. 2. or No. 3. pigs.

The following are comparative estimates of the cost of making pig-iron in the neighbourhood of Merthyr, South Wales, and in the neighbourhood of Glasgow:

At Merthyr.

3 tons 7 cwt. 0 qrs. of	Mine (raw), at 10s.	L.1	13	6
2 ... 16 ... 0 ...	Coal, at 6s.	0	16	6
1 ... 5 ... 2 ...	Limestone,	0	1	4
	All other charges,	0	9	1
		L.3	0	5

Glasgow District.

3 tons 10 cwt.	Mine (raw), at 4s. 6d.	L.0	16	3
5 ... 15 ...	Splint-coal, at 2s. 5d.	0	14	0
0 ... 14 ...	Limestone, at 3d.	0	3	6
1 ... 10 ...	Coals for the engine,	0	3	0
	All other charges,	1	1	0
		L.2	17	9

Both of these estimates presume the iron to be made with cold air, coke, and the mine roasted in the usual way.

The process of smelting iron, even on the large scale of manufacture, where tons of the raw material are subjected to an intense heat in the blast furnace, is an operation affected in the result by more delicate circumstances than is generally supposed. The proportions of the materials must, as we have seen, be in every case most accurately determined; and even then, with his furnace in good order, the tuyeres of the right length, and the blast steady and regular, is it difficult for the founder to predicate the quality of the resulting iron. With the same charge, the same blast, the same furnace, and the same management, the pigs may be of the very best quality, or of the very worst.

There are other questions to be taken into consideration, as, for instance, What is the season of the year, the direction of the wind, the hygrometric state of the atmosphere? For it is a fact well warranted by experience, that all these circumstances affect the working of a furnace.

A furnace will produce, on an average, more and better iron in winter than in summer; the atmosphere being of a higher temperature in the latter season, and consequently capable of holding a greater quantity of moisture in solution. To this greater or less degree of humidity in the air supplying the blast-cylinder, is to be attributed the difference of product so generally observed at different periods of the year. There are many facts confirmatory of this. Thus, to regulate the influx of blast to the furnace, a machine called a water-regulator was formerly much employed, and, indeed, is not yet entirely done away with. The principle of this apparatus, as in the common gasometer, is by the pressure of a column of water, to produce an unintermitting stream of air from a large vessel into which it is forced by the blast-engine. The water-regulator has fallen

Manufacture. into disuse, chiefly for this reason, that the air, in passing through it, imbibes a large quantity of moisture, which, being carried into the furnace, deteriorates the iron. Again, when the hot blast was first brought into action, the water tuyeres (see Plate CCCXVII. fig. 4.), which the intensity of the heat rendered necessary, frequently burst, and the water was of course thrown into the furnace. Whenever this happened, the very worst kind of iron was produced.

Cast-iron, as it comes from the furnace hearth, is by no means a pure carburet of iron. The nature of the process is such as to render it liable to an intermixture of various extraneous ingredients. Thus, in newly cast pigs, fragments of charcoal, undecomposed ore, and earthy matter, can in general be detected by the eye alone; whilst analysis as generally makes known the presence, in greater or less proportion, of manganese, sulphur, or phosphorus. Three principal varieties of cast-iron exist, distinguished from each other in various particulars of colour, strength, and general capability of adaptation to the purposes of art. Grey, or No. 1. pig-iron, is comparatively dark coloured, and when broken, exhibits a large open grain. It is easily rendered fluid, runs freely and with such facility into moulds, that it is the sole material of all the smaller and more delicate sorts of foundry goods, which, when composed of No. 1. metal alone, are distinguished by great smoothness on the surface. It is tough, slightly capable of extension, and so soft as to admit of filing, chipping, turning, &c.; hence it is of extensive application in the formation of machinery, particularly such parts as are small, and require much fitting up. White, or No. 3. pig-iron, is in every respect precisely the reverse of what has just been stated concerning No. 1. It is characterized by its white silvery-like lustre, more crystalline structure, and by a brittleness so excessive, that it cracks like glass on any violent blow, or sudden alternation of temperature. The file glances from its hard and flinty surface without making any impression; and its fluidity, when melted, is of so viscid and imperfect a kind, that it runs with comparative difficulty into moulds. No. 2. or mottled cast-iron, is a variety seemingly intermediate between Nos. 1. and 3. Its colour, as the name imports, is not equable, but blends in unison two distinct shades of grey, which, individually, are those of Nos. 1. and 3. The degree of hardness is greater than in No. 1, though less than in white pig-iron. In this metal we find united, to a certain extent, the qualities of hardness and toughness. When mixed largely with No. 1. iron, a proper material is furnished for artillery, steam-engine cylinders, &c. In fact, by melting the different varieties of cast-iron together in various proportions, the founder is always able to procure a material suited to his purpose, whatever be the property required. This is also in some measure accomplished by the diversity of character belonging to iron from different districts. Thus the Staffordshire metal is generally remarkably fluid, and makes excellent small castings. The Welsh pig-iron is strong, and produces bar-iron of a very tough and good quality; whilst the Derbyshire, the Shropshire, the Scotch, and other irons, all differ in like manner, each being distinguished for the possession of some property not common to the rest.

From what has been said, it will be seen that grey and white cast-iron are more especially distinguished from each other. The different aspects which they assume in every particular, such as colour, strength, and fusibility, was long accounted for by supposing the grey metal to be more highly carbonized than the white. From experiments, however, of good authority, it would appear that, so far from this being the case, there is actually, in many instances, an appreciably greater quantity of carbon in the white than in the grey. Respecting the wide diversity in external appearance and physical properties which the metals exhibit, chemists are disposed to attribute it to the mode of combination of the constituent elements, rather than to any absolute difference in amount of carbon; and they say that *there is no essential difference* in this respect, for these reasons, that the white variety may be changed into the grey, by exposure to a strong heat, and cooling slowly; whilst the grey may be changed into the white, by being heated and rapidly cooled.

The latter circumstance, indeed, is no matter of speculation, being frequently taken advantage of in the arts, as presenting a convenient method of case-hardening wheels, rolls, plating anvils, &c., to effect which, it is simply sufficient to run the metal into a thick cast-iron mould, instead of one of loam or sand. This process is called chilling. As a mould, malleable iron, when the required shape can be given to it with facility, is preferable, because, being a better conductor of heat, it chills the metal in contact with it more rapidly, and is less liable to crack from the sudden change of temperature. That there is a difference in the mode of combination of the constituents in grey and white cast-iron, amply sufficient to account for the diversity in mechanical properties which they present, experiment testifies. "According to Karsten, the carbon of the latter is combined with the whole mass of iron, and amounts, as a maximum, to 5.25 per cent.; but in some specimens, its proportion is considerably less. The former, on the contrary, contains from 3.15 to 4.65 per cent. of carbon, of which about three-fourths are in the state of graphite, and are left as such after the iron is dissolved by acids; whilst the remaining fourth is in combination with the whole mass of metal, constituting a carburet, which is very similar to steel. Grey cast-iron may hence be regarded as a kind of steel, in which graphite is mechanically mixed."[1]

The first operation which cast-iron undergoes in rendering it malleable, is that performed in the refinery, the object of which is to drive off a portion of the carbon.

The refinery is a small, low furnace, with a hearth of fire-brick, about three feet square. There are two sides of cast-iron, opposite to each other, and made hollow, so as to allow the passage of a constant stream of water through them. This is necessary, in consequence of the intense heat to which they are subjected, and which, were there no such protection, would speedily burn them through. Each side is furnished with three water tuyeres, in which as many blast-pipes of an inch in diameter are inserted. The front of the furnace is left open, but at the back are iron doors, through which the hearth is charged with the necessary complement of pigs and coke. A low, hanging chimney surmounts the hearth. The description given is that of the double refinery; in the single refinery, the blast enters only at one side.

The pigs to be refined being placed with the necessary proportion of coke on the hearth, are brought into a state of fusion, and the blast, which enters here at the same pressure as with the smelting furnace, is kept in action, until a considerable quantity of carbon has been burned out. The metal is then run from the hearth into a shallow oblong mould of cast-iron, about eight feet by two feet, which is kept cool by water running underneath. During the continuance of the operation, a lambent blue flame plays on the surface of the fused metal, indicating the combustion of carbonic oxide; and when the metal is run out into the mould, a quantity of scoria, or oxide of iron, collects at the top and floats there, a necessary consequence of the unequal rate of contraction in the two substances.

In the refinery, then, there are two effects produced. Carbon in moderate quantity is separated from the general mass of the iron, whilst, at the same time, a portion more

[1] See Turner's *Chemistry*, 5th edition.

Manufacture.

exposed than the rest becomes decarbonized to such an extent as to be free for combination with the oxygen of the atmosphere; and hence the production of cinder, which, it must be remembered, is also partly owing to impurities existing originally in the pigs. The metal which works with the least trouble, and to the greatest yield in the refinery, is No. 1, or grey pig; next to it stands No. 2, or mottled. As for white cast-iron, they are obliged to mix it largely with pig of a superior quality; when alone, it becomes thick, and does not flow readily from the hearth. The time from the commencement of the operation to the "running-out," varies a little with the kind of metal and strength of blast employed; it may be said to average about two hours. The yield of coke and metal also varies in the same manner, and much depends on the attention of the refiner. Taking the best grey pig, the average yield to the ton of refined metal may be stated at 22 cwt.; the quantity of coke consumed will be from 9 to 10 cwt.; the charge or quantity of metal worked off at once is 25 cwt. Below are actual practical statements of the refinery yields at one of the largest works in Merthyr.

In the year 1823,

	Tons.	cwt.	qrs.		Cwt.	qrs.	lb.		Cwt.	qrs.	lb.
Refined Metal made in April, . .	975	9	2	Yield	22	1	15	Yield of coal,	9	1	26
May, . .	1015	10	2	...	22	2	25	... ...	9	1	22
June, . .	885	10	0	...	22	2	22	... ...	9	1	20
July, . .	946	15	0	...	22	2	4	... ...	9	0	2
August, .	942	16	0	...	22	0	6	... ...	9	2	6
September,	971	15	2	...	22	1	10	... ...	9	1	20
October, .	996	19	2	...	22	1	0	... ...	9	0	12
Average yield on	6734	16	0	is	22	1	0	Average coal,	9	1	8

In the year 1824,

	Tons.	cwt.	qrs.
The quantity of pigs used was . . .	14,073	9	3
Finers' metal produced, ...	12,592	11	2
Total waste on 14,073 tons 9 cwt. 3 qrs. .	1,480	18	1

Shewing the average yield to have been 22 cwt. 2 qrs. 24 lb. of pigs to the ton of refined metal.

	Cwt.	qrs.	lb.
In the year 1825, the yield was . .	22	1	2
1826, ...	21	3	1
1827, ...	21	3	8

And the yield continues much the same to the present day, the chief saving being made in the puddling-furnace; a portion of which is, however, again lost in the mill-furnace.

Refiner's metal is totally unlike the pig from which it was produced; it is as white as or whiter than No. 3. cast-iron, and so brittle as to be broken in pieces by a single stroke of a hammer. It is in fact, in every external particular, so similar to white or No. 3. metal, that, for some inferior kinds of iron, the refining process is altogether omitted, the metal as it comes from the blast-furnace being merely run into moulds of cast-iron, which, as before explained, chills, and renders it hard, brittle, and white. A considerable proportion of forge-pigs, as they are called, undergo no other refining process than this, if that can be called refining, which probably merely alters the arrangement of the elementary molecules, without removing a particle of carbon. The plate of refined metal is always more or less honeycombed and cellular on the surface. When this fretted and unsound texture extends to any great depth, the plate does not puddle well; it is pointed out as too much blown to be good.

The cinder or scoria produced during the refining of iron, formerly accounted of little or no value, is now made to reproduce great part of its iron in the blast-furnace. For this purpose, however, it is necessary to mix it very largely with earthy matter or common mine; because, when smelted alone, it is found, as seems also to be the case with the pure native oxides, to burn the furnace, and to produce the most ineffective result, both with regard to quantity and quality of yield. Made use of even in sparing proportions, the metal produced is rarely No. 1, or foundry-iron. The quantity of cinder generally used in the Welsh furnaces, is from 5 to 6 cwt. to the ton of good calcined mine; and, of course, the proportion of limestone to the charge need not be so much as usual. As the refiner finishes his plates of metal, they are weighed, and, if there be no stock on hand, carried directly to the puddling-furnace, where they lose carbon to a still further extent. Refined metal is said, like steel, to improve in quality by exposure to the atmosphere, and to be better fitted thereby for the next operation which it undergoes. Accordingly plates of metal which have been on hand for any length of time are preferred by the puddler; They work more easily, and produce a better quality of bar-iron, than if puddled directly from the refinery.

Puddling is performed in a common reverberatory-furnace, of which Plate CCCIX. figs. 3, 4, 5, are a section and elevation. In fig. 3, *a* is the grate, supplied with fuel by an aperture, also marked *a* in fig. 4, called the stoke-hole; and *b* is the body of the furnace, where the gradual narrowing of height, by means of the arched ceiling, causes the flame in every part to beat on the hearth, or material placed there to be heated. C C, figs. 3 and 4, is a door of iron, through which the puddler charges his hearth, and performs other manipulations incidental to his process. It is opened and shut by raising or depressing the lever, to which the chain *d* is attached. The sides of the furnace are large plates of cast-iron, lined with firebrick; the plates E are protected from the heat, by having their lower sides immersed to a certain depth in a metal groove or socket, around which water is kept flowing. The hearth is of cast-iron, covered with a glaze or coating of finery cinder, to protect it from fusion. After the puddler has brought his furnace to the necessary temperature, he introduces his charge of metal broken into

Manufacture.

small fragments, at the same time regulating the influx of air through the grate and stoke-hole, by means of the damper in the chimney, so as to produce a most intense heat. In about twenty minutes, the charge begins to shew signs of melting; and the whole being brought into a state of fusion, the puddler, with a long iron hoe-shaped instrument, keeps stirring up the imperfectly liquid mass, and incessantly presenting fresh surfaces to the action of the fire. Whilst he thus operates with the metal, it heaves and swells, and emits flashes of blue flame, shewing, as in the refinery, the formation and combustion of carbonic oxide. The stirring being still vigorously kept up, all appearances of an elastic fluid at length cease, the metal becomes curdy and clotted, and so totally deprived of cohesion, as to crumble away beneath the instrument of the puddler like dry earth.

The damper, which had been nearly shut, is now raised, fresh fuel is put on the fire, and an intense heat begins again to be excited. At this stage the puddler occasionally throws a little water on the charge, which now, in a fine granular state, is said to be coming round to nature, and as the temperature rises, every exposed point of surface assumes the vivid whiteness of welding iron. Presently the separated particles begin to coalesce, and to form into small masses, which work more and more heavy, until the whole are at length fashioned by the puddler into rude balls or blooms, which are carried at once to the shingling forge and rollers, there to be beaten and drawn into bars. The charge introduced into the puddling-furnace is 4 cwt., either wholly of refined metal, or mixed with a portion of No. 3, or forge-pig. The best kind of iron is produced without any the least particle of cinder or oxide being used; but the temptation to make profit is so irresistible, that the iron-master allows his puddlers to introduce a large portion of cinder from the forge and rollers, to improve the yield. The consequence is, that the quality of the iron is deteriorated, whilst the puddler frequently brings as much or more iron out of the furnace than his charge of metal amounted to.

White cast-iron also, and forge-pig, when used in large quantity, tend to the production of a weak and inferior kind of iron; nor is this the only disadvantage attending their employment, the waste which they are subject to being very great. A considerable degree of certainty is given to the puddling furnace results by the previous operation of the refinery, because there the different qualities of cast-iron, blended in proper proportions, are reduced to one common standard, comparatively uniform in texture, and always presenting to the puddler a sameness of constitution in the material which he employs. Using cast-iron indifferently as it came from the blast furnace, was the great defect of puddling when first introduced; nothing connected with the operation could be reckoned on with safety; the waste was great, the quality of puddled iron irregular, and the duration of the process tedious. Notwithstanding this, however, it has of late been attempted to run the iron directly from the smelting into the puddling furnace, omitting the refinery altogether. Furnaces constructed with this view, have been erected in Staffordshire.

The toil and labour of puddling is excessive, and the men require to be frequently relieved; four sets or shifts of men, each set being six hours in and eighteen out, will run twenty heats, or from 80 to 85 cwt. in the course of the day. To effect this, the furnace ought to be double, or so contrived that, whilst one charge is puddling, a fresh one is heating and preparing for the same operation.

Three qualities of British bar iron are recognised in commerce, No. 1, or puddled iron; No. 2, and No. 3. A tough and fibrous quality called cable iron, is also made. The manufacture of these will now be shortly described.

The rough balls of iron, just as they are formed in the puddling furnace, are carried directly to the shingling forge, where they are knobbled into oblong blooms, and from thence, without reheating, passed successively through the puddling rolls; first through a set of gradually decreasing elliptical holes, which rough them down, then through flat openings or groves, (see Plate CCCXI. fig. 3.) by which they are formed into long flat bars, 3, 4, or 5 inches in breadth, and from one-half to three-fourths of an inch in thickness. These bars are, of course, very ragged and unequal in texture, and still retain incorporated with them a considerable quantity of cinder, acquired in the puddling furnace, although much has been forcibly squeezed out by compression between the rollers. They are called No. 1, or puddled, or mill-bars, and though exported to some extent as a cheap article, are looked upon as requiring at least another process before they can be called finished iron. For this purpose they are carried to a large pair of shears (see Plate CCCXII. fig 3.) where, being cut into lengths proportional to that of the intended bars, they are piled up with reference to the required thickness, and introduced into the mill-heating furnace (see Plate CCCXII.), where they are subject to a further loss of cinder or oxide, which, combined with sand, runs from the furnace in a fluid state. A period of from fifteen to twenty minutes is sufficient to bring the piles to a welding heat; they are then carried to another set of rollers, similar to those first described, and from thence to the finishing rollers, where they receive the most perfect form and accurate dimensions. These constitute No. 2. bars; when cut up, piled, reheated, and again passed through the rollers, No. 3. bars are formed, and the iron may then be said to have arrived at the maximum of strength and value possible to be given to it in the actual processes of manufacture; that is, supposing it to have been made from pure mine alone, without any admixture of cinder, either in the smelting or puddling furnaces. It must indeed be kept in mind that the best iron is invariably that which has been produced from the purest materials. If the ironstone or coke is bad, if they contain sulphur, phosphorus, arsenic, or any other equally deleterious ingredient, it may safely be pronounced that the pig-iron will be bad, that the refined metal will be bad, and that the bar-iron, no matter how many times it may have been hammered, rolled, heated, piled, and rerolled, will still be accompanied by the refractory ingredient which existed in the raw material.

There is undoubtedly a practical limit to the good effect produced in iron by beating and drawing out. All that rolling does, is merely to squeeze out the cinder and impure matter, blended with the rough bar, and thus to force the fibres into a more perfect state of juxtaposition. The strength which such a process imparts, is thus due entirely to a mechanical cause, and iron which has undergone the operation may be indeed very tough and flexible at a certain temperature; but cool it below, or elevate it above this, and you bring it within the sphere of a new and hitherto quiescent power; the deleterious substances, originally in the ore, come into play, you find that the iron is either cold-short or hot-short, and in fact that the whole of its good qualities are gone. In contradistinction to this, an iron that has been smelted from the most suitable and purest materials, and has gone through the usually prescribed course of manufacture, will be not only mechanically but chemically good. Its malleability will not be limited to one range of temperature, and its strength and toughness will be owing not more to the agency of rolling, than to the absence of all substances, by which such qualities could possibly be impaired.

In the contracts of the Admiralty for chain cables for the British navy, it is stipulated as an express condition, that "the iron shall have been manufactured in the best manner from pig-iron, smelted from ironstone only, and selected of the best quality for the purpose, and shall not have received in any process whatever subsequent to the

Manufacture.

smelting, the admixture of either the cinder or oxides, produced in the manufacture of iron; and shall also have been puddled in the best manner upon iron bottoms, and at least three times sufficiently drawn out at three distinct welding heats, and at least twice properly fagotted."

The following is a table of the breaking proof of chain cables, and of the iron for the purpose of making them; also of the proofs required by his Majesty's navy for chains.

Size of Bolt.	Proof of Bolt.		Proof of Chain.		Navy proof of Chain.
Inches.	Tons.	Cwt.	Tons.	Cwt.	Tons.
$\frac{1}{2}$	5	7	8	11	$4\frac{1}{2}$
$\frac{5}{8}$	8	7	13	4	$5\frac{1}{2}$
$\frac{3}{4}$	12	1	19	5	$10\frac{7}{8}$
$\frac{7}{8}$	16	4	26	5	$13\frac{3}{4}$
1	21	8	34	5	18
$1\frac{1}{8}$	27	2	48	15	$22\frac{3}{4}$
$1\frac{1}{4}$	33	10	53	11	$28\frac{1}{2}$
$1\frac{3}{8}$	40	10	65	0	34
$1\frac{1}{2}$	48	4	77	0	$40\frac{1}{2}$
$1\frac{5}{8}$	56	11	90	10	$47\frac{1}{2}$
$1\frac{3}{4}$	65	12	105	0	$55\frac{1}{8}$
$1\frac{7}{8}$	75	6	120	10	$63\frac{1}{4}$
2	85	14	137	0	72
$2\frac{1}{8}$	96	15	155	0	$81\frac{1}{4}$

Besides the three varieties of bar-iron which have been noticed, several works, chiefly in Wales and Gloucestershire, make a very tough and strong quality called charcoal-iron, chiefly used for the manufacture of tinned plates, and of horse-shoe nail-roads. Charcoal-iron is made from the best pigs, and refined in the usual way; but, as a substitute for puddling, it undergoes a second refining process, in which charcoal, not coke, is used; the resulting bloom is taken to the forge hammer, drawn out into a slab, and is then ready for the manufacture of this plate.

The great defect of bar-iron, as before hinted at, is the limitation of malleability to one temperature. Cold-short is the term applied to iron which is brittle when cold, though malleable at a red heat. The defect is generally owing to the presence of phosphorus, but may be occasioned by remaining too long in the furnace.

Silica also renders iron cold-short. Thus, in producing a welding temperature, it is common to throw a little sand on the parts most exposed to the heat. A slag is thus formed on the surface which protects iron from wasting; on this account, however, that part of a bar where a weld has taken place, will always be found to be more brittle than any other. Red-short iron is malleable enough at common temperatures, but liable to crack and fly, when punched or beaten at a red heat. This quality is at once detected in giving to a bar any particular form. Thus, in turning links (which is done by machinery), numbers are frequently to be rejected on account of cracks at the outside of the bend.

The waste in the balling or heating furnace is much the same, whether Nos. 1 or 2 bars be taken; but the production of cinder ought seemingly to be greatest in the case of No. 1, as being a much more impure material, and such probably would be the case, had not puddled bars a comparatively loose and open texture, in consequence of which they are sooner heated, and remain a shorter time in the furnace. Sixteen tons, 7 cwt. 3 qr. 7 lb. of No. 2 iron were cut down, piled, heated, and rolled into bars; the produce weighed 15 tons 7 cwt. 3 qr. 7 lb., and consequently the yield to the ton was 21 cwt. 1 qr. 12 lb. Speaking generally, bar-iron may be said to work to a waste of from 1 to $1\frac{3}{4}$ cwts., allowing for differences in the purity and heating power of the coal, sizes of piles, &c.; for, when the pile or billet is very small, there will be a greater waste proportionally to the comparatively greater surface exposed in the furnace; and this, with increased trouble and loss of time in rolling, enhances very much the price of the smaller descriptions of iron.

From what has been said of the various deteriorating circumstances which are incidental to the manufacture, it will readily be conceived that bar-iron is by no means regular in quality. The following trials of round-iron, performed in the years 1832, 1833, and 1834, present some curious results, and certain cases particularly would seem to indicate that the having gone through an additional process of rolling, is not always a guarantee of superiority. The iron was all of Welsh manufacture, though from different companies, and the experiments were made in a testing machine on the lever principle.

Result of Experiments on the strength of Iron, intended for Chain Cable.

December 10. 1832.

$1\frac{1}{4}$ in bolt, in the state of No. 3, cable (mine) iron, broke with $30\frac{1}{2}$ tons.

$1\frac{1}{4}$ in bolt, the same material, but put through another process, $31\frac{1}{2}$ tons.

$1\frac{1}{4}$ in bolt, in the state of No. 3, cable (mine) iron, broke with $32\frac{1}{2}$ tons.

$1\frac{1}{4}$ in bolt, another trial, $31\frac{3}{4}$ tons.

January 5. 1833.

$1\frac{1}{4}$ in bolt, in the state of No. 2 (mine) iron, broke with $34\frac{1}{2}$ tons.

$1\frac{1}{4}$ in bolt, in the state of No. 2 (mine) iron, broke with 31 tons.

January 11.

$1\frac{1}{4}$ in bolt, in the state of No. 2 (mine) iron, broke at $34\frac{1}{4}$ tons.

$1\frac{1}{4}$ in bolt, in the state of No. 3 (mine) iron, broke at 31 tons.

Two trials of these with similar results.

January 11. 1833. Continued Experiments.

$1\frac{1}{4}$ in bolt, in the state of No. 3 (mine) iron, broke with $32\frac{1}{2}$ tons.

$1\frac{1}{4}$ in bolt, same material as the last, but put through another process, broke at $32\frac{1}{2}$ tons.

$1\frac{1}{4}$ in bolt, in the state of No. 2 (mine) iron, broke with $23\frac{1}{2}$ tons.

$1\frac{1}{4}$ in bolt, in the state of No. 2 (mine) iron, broke with $32\frac{1}{2}$ tons. The latter bolt had been previously, when in the state of No. 1 iron, rolled down much smaller, and was consequently more worked in the roll.

January 14. 1833.

No. 1. $1\frac{1}{4}$ in bolt, in the state of No. 2 (mine) iron, broke with $32\frac{1}{2}$ tons.

No. 2. $1\frac{1}{4}$ in bolt, in the state of No. 2 (mine) iron, broke with $30\frac{1}{4}$ tons.

These bolts, No. 1 and No. 2, were the produce of one pile, laid up above the ordinary size. After the pile was heated carefully, and roughed down to three inches diameter, it was taken to the shears and divided into two pieces. The No. 1 piece was instantly, and at the same heat, rolled off; the other half was rolled into a flat bar at the same heat. It was then cut down, piled, and rolled into a bolt, and on subjecting both pieces to the testing machine, it appeared to support a less strain than the No. 1 bolt.

One of the great advantages of the present system of manufacture, as compared with that of some fifty or more years ago, is the facility and cheapness of rolling. At

Manufacture.

every great ironwork it has become necessary to have not only rolls for the manufacture of bar, bolt, and square iron, but also for numerous other articles, such as railway bars, boiler plates, sheet-iron, hoop-iron, &c. Slit nailroads are made with great dispatch, a number being cut at once from a thin bar of iron, which is passed hot between revolving cutters (see Plate CCCXIV. figs. 1 and 2). Boiler-plate rolling is most laborious work. The plate is rolled from a slab prepared previously under the forge hammer, and weighs generally from 1 to 4 cwt. Instances have been known of the slab weighing so much as 11 cwt.; the passage of so large a mass of matter between the rolls causes an enormous strain, and unless the mill pinions be of the strongest metal, there is great risk of their breaking. The various shapes and forms of rolled and hammered iron, turned out by an ironwork in active operation, are numerous beyond description. Any peculiarity of form suggested by the engineer, if the inducement be strong enough, is sure to be accomplished in some one of the many ironworks in the kingdom, and that with a dispatch and cheapness of execution which it would once have been thought impossible to attain. Shafts and beams, weighing from 3 to 4 tons, are now manufactured under the forge-hammer in from three to four days, that thirty years ago would have employed from fourteen to sixteen men for as many weeks. An establishment capable of throwing off weekly 200 tons of finished bars, bolts, boiler plates, sheet-iron, nailrods, cooper's hoops, &c. will require five blast furnaces; this is, supposing nearly 1¼ ton of pig-iron to produce a ton of bar-iron, and that a thousand tons per year are consumed as castings at the work. The necessary machinery for the manufacture of these goods are shewn in the plates annexed to this article.

Having thus considered the manufacture of pig and bar iron, some details are requisite in connexion with the improved method of smelting by heated air.

The origin of the invention, with the circumstances which led to the discovery that hot air does not, as once generally supposed, deteriorate iron in a liquid state, have already been dwelt on in a preceding article (see GLASGOW). Nothing remains, therefore, but to mention some of the results which have been arrived at, and to detail the present mode of applying the discovery, which is alike applicable to smelting, refining, and to the working of bar-iron.

Plate CCCXVII. fig. 1, shews the plan of a cupola furnace in connexion with the hot-air apparatus, as at present in operation in several works in Glamorganshire; and *a*, *a*, *a*, &c. the metal pipe in which the air is heated as it passes from the blast cylinder to the cupola. At intervals along the range are placed the heating furnaces, *b*, *b*, *b*, &c., the flame and smoke from which are carried along a brick conduit or flue to the chimney, in the direction shewn by the arrows. The furnace has three working tuyeres. Near the entrance of two of these, the main pipes are laid down in a short double row, in each case, connected together by four smaller pipes, directly opposite to which are placed two of the heating furnaces.

Thus the air, on arriving here, already at a high temperature, is divided amongst several small tubes, exposing a much greater surface to the action of the fire than could conveniently be done in one single pipe.

Hence it becomes still more intensely heated, and the interval being so short, has no time to cool before entering the furnace.

With this apparatus water tuyeres are necessary, the air being heated to upwards of 612° Fahrenheit. Fig. 4. is a section of the water tuyere, shewn also in the other figures. It is merely a short duplex pipe of cast-iron, placed at the entrance to the furnace, and having a stream of water continually flowing through the interval formed by the two surfaces.

When the heating apparatus was first employed, the contraction and expansion to which the pipes were liable, from fluctuations of temperature, was so great, as very materially to derange the joints, which were then common flanches, bolted together in the usual way. Each length of pipe is now made with a small bead and dovetail groove at the extremity; and as the laying down proceeds, the joints are firmly secured by having a solid ring or fillet of metal cast on (see fig. 3).

Thus the whole range is as a single pipe, and the expansion is only felt at one extremity, where it is provided for by a stuffing-box, or enlargement of the engine blast-pipe, into which the heated air-pipe is inserted with the necessary play.

The advantage of heating the air for smelting arises chiefly from the great economy of materials produced.

This has been invariably the case wherever the improved process has been adopted, the economy becoming more apparent, proportionably with the elevation of temperature given to the air. In the first place, the consumption of coal and limestone, especially of the former, is considerably lessened. In the neighbourhood of Glasgow, the aggregate

Ores of Iron, Coal, &c.

of materials required to make a ton of pig-iron is now little more than one-half of what was necessary when cold air was used. Much the same is the result of using the hot-blast in Derbyshire and Staffordshire. The following is an estimate of the quantity of materials required in the year 1829, to make a ton of pig-iron, with coke and cold air; and, in 1834, with crude coal, and the air heated to 612°. This statement refers only to the Glasgow district.

	With cold air.		With hot air.	
	Tons.	Cwt.	Tons.	Cwt.
Splint coal for smelting, .	5	15	2	0
Roasted mine, . . .	1	15	1	17
Limestone, ...	0	14	0	11
Coal for blowing engine, .	2	0	0	11
Coal for heating apparatus, .	0	0	0	8
	10	4	5	7

It appears from the above statement, that the expense of fuel for the blowing engine and heating apparatus, added together, does not amount to so much as did the coals for the blowing engine alone, before the heating apparatus was used, the quantity of cold air required to blow a furnace being much more than when raised to an elevated temperature, on account of the increase of volume attendant on the latter condition. To such an extent, indeed, is this the case, that blowing machines, which were only capable of working three furnaces, when cold air was used, blow with ease four furnaces, when the blast is heated to 612°.

The decrease in the requisite quantity of iron-making materials is accompanied by an increase of one-fourth in the quantity of iron produced in a given time; a furnace that with cold air made sixty tons of metal per week, now making as much as eighty tons during the same period. Whether the metal produced by the hot-blast be equal to that made in the usual way, admits of some doubt. The general opinion seems to be, that the iron is weaker, both in the pig and in the wrought bar.

There appears to be no possible reason why this should be the case, provided that coke only be employed in the blast-furnace. If the coal be used in a raw state, as it most commonly is, when the furnace is blown by hot air, then there certainly is room for suspicion that deleterious substances may come in contact with the iron, which, had the coal been coked, would, during that operation, have been in great part, if not wholly removed.

III.—ORES OF IRON, COAL, &c.

Although it is not intended in this part of the work to enter into a minute mineralogical examination of the various ores of iron; yet it seems necessary to a right comprehension of many facts and processes connected with the manufacture of that metal, that we should be acquainted to a certain extent with the chemical and physical characters of its most useful ores, and also of the fluxes and other adjuncts employed in their reduction. Notwithstanding the numerous forms in which iron occurs mineralized, and extending as it does in one or other of these, throughout the whole suite of rock formations, yet there are many circumstances which limit the sources of its supply within narrower bounds than would otherwise have existed, had there been no such difficulties to contend with. Sometimes the minuteness of the quantity, disseminated through a rock or stratum, is such as to preclude every idea of its being made profitable to the miner; whilst at other times the substances composing the ore, and existing in contact or combination with its metallic ingredient, are of a nature calculated to impart deleterious qualities to the iron with which they are associated.

Ores of Iron, Coal, &c.

Conceding, then, to these and other similar circumstances, their due weight, it arises that all the ores actually made available to the production of iron, may be essentially comprehended under two great divisions; the one including those which, like the magnetic and specular, consist simply of iron in direct union with a greater or less definite proportion of oxygen; the other, those which, like the ironstones of secondary formations, consist of oxide of iron in union with carbonic acid, and in contact or mixture with numerous earths, &c. hereafter to be enumerated. The kind of ironstone existing in any district may in general be inferred from the geological character of the country. Thus the primary countries of Sweden and Scandinavia furnish us with the purest of all the iron-ores. In the transition districts of Lancashire and Cumberland we meet with a mineral, less, though scarcely less pure; and in the coal-fields of Europe, America, and New Holland, with the most impure, yet certainly most valuable source of iron. The iron-ore occurring in Cumberland and Lancashire is the red glance, or hæmatite. In composition it is nearly a pure peroxide, affording a small per-centage of silica, water, and, according to Chevalier, a little ammonia. It possesses in general a high lustre, assumes the reniform and botryoidal shapes, and frequently contains crystals of quartz. Its situation in Cumberland and Lancashire, at a distance from coal, precludes it from being smelted in these districts to any great amount. Hence it is shipped, in the former county, at Whitehaven, and at Ulverstone, in Lancashire, for different parts of the kingdom, where it is generally mixed with ironstone of a more meagre quality. Much ore from Workington in Lancashire is smelted in South Wales. The same material from the same neighbourhood is to be met with in Worcester, Shropshire, Staffordshire, Northumberland, Scotland, &c. The argillaceous ironstone is, with the exception of coal, the most important mineral product of our island. It is the source whence all the great iron districts of this country, Staffordshire, Wales, Shropshire, Derbyshire, Scotland, &c. derive their almost inexhaustible supplies. Occurring chiefly in the coal measures, it exists to a greater or less extent throughout the whole of the carboniferous group, forming in the different members of that series beds and layers of lenticular nodules, conformably with the other strata, which consist of argillaceous and bituminous shales, micaceous sandstones, and different varieties of clays, and coal. Every coal-field has thus the materials for the iron manufacture within its own geological limits, an abundance of metalliferous ore, coal to roast, reduce, and carbonise it, sandstone for building, refractory fireclays for the furnaces, and mountain limestone for fluxing the ore, generally at no great distance.

The ironstones of coal districts have been divided into classes, according as the different earths preponderate in their composition.

1*st*, Argillaceous Ironstone, having fine clay as its chief component earth, lime in the next proportion, and nearly destitute of silica, when properly torrefied, exhibits fibres on its internal surface, of a brown, dark brown, or claret colour, running either in streaks, or radiated and adhering tenaciously to the tongue, will afford, with a moderate proportion of lime and coke, iron of the first quality, possessing strength conjoined with an intimate degree of fusibility.

2*d*, Calcareous Ironstone, that which contains lime as its principal earthy mixture, and holds clay in the next proportion, but is comparatively unalloyed with sand; when regularly torrefied, it assumes a variety of shades, generally lighter in colour than the former class, sometimes presenting internal fibres, and adheres less tenaciously to the tongue. Its vein can always be reduced and carbonised

es of I, Coal, &c.

with a comparatively small quantity of limestone and coke. Under this class are found those which produce iron of a fusible nature, seldom connected with strength, but valuable for fine castings, which require ornament more than durability.

3d, Those ironstones, the component parts of which are nearly an equalized mixture of clay, lime, and sand, which torrefy with a slight degree of adhesiveness to the tongue, assuming a darkened ore-brownish colour, void of every internal fibre, always afford an iron of an intermediate quality for fusibility and softness, but possessing strength in an eminent degree, and excellently adapted for artillery and the larger parts of machinery.

4th, Ironstones which unite a large proportion of sand with sparing proportions of clay and lime, and which, upon being exposed slightly to heat, exhibit masses of semi-vitrification, neither obedient to the magnet, nor adhesive to the tongue, having a refractory disposition, and possessing a dark blue or blue colour, always afford, with the usual proportion of fuel, iron of the worst quality either as to strength or fusibility. Such metal is commonly brittle, and affords malleable iron of the cold short quality.

It is a matter of fact that phosphorus sometimes exists in iron to so great an extent, as very materially to injure its malleability at low temperature, rendering it, according to technical language, cold-short. That phosphorus is actually the agent productive of this effect, was ascertained by the experiments of Bergmann and Meyer, who were invariably enabled to detect a phosphuret in iron possessing the above-named quality. The existence of phosphorus in iron is a sufficient evidence of its presence in the ores of that metal, and would lead us to infer that there was a gradual deposition of animal matter during the formation of the ironstone beds. In this inference we are amply supported by observation; for traces of animal matter have been found very extensively in ferruginous beds and nodules, traces more particularly of membranous shells, and of the scales and bones of fish.

In the Mid-Lothian coal-field, ironstone nodules are described as occurring in great number, and, when broken open, exhibiting a very curious appearance. The mass of the stone is of a dark brown colour, compact and solid; in the centre, generally occupying about an inch, is an oblong body, the structure of which is disposed in laminæ, or concentric layers. The round body, the appearance of a neck and head, the four projecting substances corresponding to legs, and the circular rings on the part corresponding to the abdomen, all evidently corroborate the supposition that the centre substance is an animal in a petrified state, or some organic substance which has served as the nucleus of the stone.

In the *Annales des Mines* for 1825, M. Berthier gives an account of his discovery of phosphate of lime, in association with the argillaceous ironstones of the coal formation at Riant in France. The specimen he examined had absolutely the same appearance as the argillaceous ore of iron with which it was found; and he adds that the fact, interesting as it may appear in a geological point of view, deserves also the notice of metallurgists, and should induce them to institute a strict examination of the ores with which the coal formation furnishes them.

The specimen of phosphate of lime, on being analyzed, gave the following result:

Lime,	0.363	Phosph. lime (Apatite),	0.670
Phosph. acid,	0.310	Carb. of Iron,	0.157
Protox. iron,	0.096		
Alumina,	0.090	Alumina,	0.190
Water, bitumen, and carbonic acid,	0.120	Water and bitumen,	0.060
	0.979		0.979

The mineral is found in nodules of a globular form, sometimes flattened, and always of rather small size; and these nodules occur in great quantity in the black argillaceous schists which separate the second bed of coal from the sandstones that support it. They are not homogeneous; their crust is almost entirely composed of carbonate of iron. Sometimes they contain a great quantity of transparent laminar carbonate of lime, which divides the mass into small prisms; sometimes it is a coally matter, and at other times they are enveloped in a crust of compact sulphuret of iron. In the centre there is a nucleus of a pale yellow or grey colour; compact, fine granular, and traversed by impressions of gramineæ. It is this nucleus which contains the phosphate of lime. The crust of a nodule, assayed in a covered crucible without addition, gave 0.20 of hard cast-iron, equivalent to 0.43 of carbonate of iron; and a slag, weighing 0.56, which was opaque, of an apple-green colour, and entirely similar to melted phosphate of lime. The ore of iron called Bog Iron Ore, which is daily forming by deposition from pools, the waters of which have previously percolated through ferruginous strata, very frequently contains a large proportion of combined phosphoric acid. The iron made from this ore is cold-short, but is excellent for producing distinct and well defined castings, as it swells in cooling. The greater part of the Berlin ornaments are made from bog-ore.

In enumerating the more general ingredients of ironstones, perhaps titanium should be noticed; which, since its first detection as a new substance at Merthyr Tydvil, where it had been supposed to be a species of pyrites, has been found in the slags of nearly every furnace in the kingdom, as well as in Germany and France, a pretty evident proof of its wide dissemination in connexion with minerals affording iron.

Whether titanium ever combines with the iron during the process of reduction, and is thereby productive of a good or bad effect, we do not feel competent to assert. It seems not improbable, that its presence in small quantities may tend to improve the quality of the iron, with which it is alloyed, in the same way that certain other hard and refractory metals, as rhodium, &c. are productive of an admirable effect in common steel. Indeed, the supposed case is not without analogy, as in reference to manganese, to the presence of which Berzelius attributes in a great measure the superiority of the Swedish over the British iron.

When magnesia exists to any great extent in an iron-ore, the infusibility of the combined mine and flux are greatly increased. Presenting itself under so deleterious an aspect, this earth is unfortunately of common occurrence both in ironstones, cokes, and limestones. On this account all the members of the magnesian limestone deposits are to be most carefully avoided.

In concluding these remarks upon ironstones, it may not be unimportant to add a few observations on coal, a mineral of so much importance in connexion with iron-making, when practised in thinly wooded countries. Of the different species of coal enumerated by mineralogists, the common varieties of the black or bituminous class appear to have been most extensively employed in smelting operations, a fact resulting not only from their more universal distribution, but also from certain peculiarities in their organization, as contrasted with those coals which approximate in character to the anthracites. Nor does this preference appear to have been conceded wholly without trial. Thus, in South Wales, the extensive development of stone-coal seams, in connexion with rich deposits of ironstone, have led to frequent attempts at using this coal in the raw state as a substitute for coke. These attempts have hitherto proved unsuccessful, a result the more unexpected, considering that the coal is a dense and nearly pure mineral

Ores of Iron, Coal, &c.

carbon; and that the close-grained and more ponderous cokes have generally been regarded as best adapted for iron-smelting. It has been suggested that the imperfect conducting power of this mineral for heat, arising probably from the compactness of its texture and its want of bitumen, presents the obstacle, which has hitherto prevented its application with any success to processes conducted in the blast furnace. This imperfect transmitting power is so great, that the application of the blast to a furnace, in which the stone coal is placed as fuel, instead of producing ignition throughout the mass, actually extinguishes the fire.[1]

In a patent taken out some years ago, it was proposed to smelt iron with stone coal, introducing at the same time a stream of carburetted hydrogen.

The following are analyses of several varieties of coal:

	Carbon.	Volatile matter.	Ash.
No. 1,	89.00	8.00	3.00
No. 2,	82.00	14.50	3.50
No. 3,	69.00	28.00	3.00
No. 4,	85.60	13.40	1.00
No. 5,	52.45	45.50	2.04
No. 6,	52.88	42.83	4.28

No. 1. is an analysis of the Welsh stone coal.

No. 2. is an analysis of the furnace or iron-making coal of Wales. A most important and peculiar property resident in this coal is the proneness to ramification or swelling exhibited by it during combustion, which frequently gives the coke an arborescent appearance, and renders it in some varieties as light and porous as wood charcoal; whilst in others, as, for instance, the great seam at Merthyr, the coke is much harder, more ponderous, and admirably adapted for iron-smelting.

No. 3. is an analysis of the bituminous or binding coal of South Wales, many seams of which possess the important property of being free from sulphur. The coke of this coal, when it can be procured, is mixed with that of the branching coal in smelting.

No. 4. is an analysis of the great seam at Merthyr, the coal from which a great portion of the coke for the blast-furnaces is procured. It is coked in heaps in the open air, and produces a close-grained coke of a silvery lustre, and very free from sulphur.

No. 5. is an analysis of the Alfreton furnace-coal, and

No. 6. is an analysis of the Butterly furnace-coal.

Besides the ingredients indicated by the analyses here given, as constituting coal, a great number of extraneous substances are commonly blended and associated with that mineral, such as sulphuret of iron, carbonate of lime, magnesia; and these of course exercise a detrimental influence when the coke is brought to play its part in the blast-furnace.

The object in coking is to obtain the carbon of the coal in as insulated and independent a form as possible, by driving off the moisture, sulphur, and gaseous constituents. The earthy ingredients not being volatilisable, of course remain, and even the sulphur is never wholly driven off. The relative amount of these substances, as indicated in some degree by the quantity, weight, and colour of the ash, when a certain portion of coke is burnt, should in every case be ascertained before a coal is appropriated to smelting operations.

The method of coking varies in different places. In some iron districts the process is performed in small ovens, the access of air being prevented as much as possible. In South Wales, on the contrary, long heaps of coal are ignited in the open air, and allowed to burn from one end to the other beneath a slight covering of turf or ashes. After the cokes have done smoking, the cokers frequently stir the heaps, in order, as they say, to allow the escape of sublimed sulphur; and, after the ignition has continued a sufficient length of time, the burning cokes are extinguished with water, which is also said to favour the escape of sulphur; perhaps in this way. A portion of the water being decomposed by contact with the cokes at so elevated a temperature, the sulphur of the coke probably attaches itself to one of the liberated gases, and makes its escape in the form of sulphurous acid gas, or sulphuretted hydrogen. It cannot fail of being perceived, that the process here described must be of a very uneconomical nature; and, indeed, if the weather happen to be very windy, no exertions can at times prevent the loss of many tons of coal in a single night.

Rollers, Forge, &c.

Coke is of various degrees of weight and quality, corresponding in great measure with the properties of the coal from which it is derived. Sometimes it has a dull grey fibrous fracture, very similar in appearance to charcoal of wood. More generally the fracture is porous, with a bright vitreous, nay almost metallic lustre. The quantity of coke that can be procured from a given quantity of coal, of course differs considerably; so much, indeed, in different seams and in different districts, as to render it difficult to give any numerical standard on the subject.

In the Glasgow Coal-field,

1½ tons of best splint coal produce 1 ton of coke.
2 tons of inferior do. .... do.
2¼ tons of the main do. .... do.
3 tons of Pietshaw do. .... do.

And it is generally observed, amongst the manufacturers of that district, that one ton of the best Scotch coals is only equal to three quarters of a ton of the best Newcastle.

The Welsh coals, as will be seen from the comparative analyses before given, contain a much less quantity of volatile matter than either the English or Scotch; and hence their great superiority as an iron-making coal.

IV.—ROLLERS, FORGE, &c.

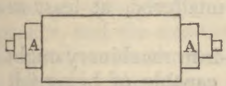
In the preceding pages we have given a description of the manufacture of iron, up to the time of producing finished bars in the rolling-mill; but as yet, nothing further has been said of the machinery employed, than the explanation of processes under consideration, rendered absolutely necessary. Supposing the manufactory in an active state of working, to turn out 200 tons of finished iron per week, it may be well to enter into some details connected with the making and fitting up of the rollers, describing at the same time that part of the establishment exclusively appropriated to this purpose. After the manufactory is furnished with the machinery in daily use, such as rollers, coupling-boxes, pinions, spindles, hammers, anvils, the parts of the different furnaces, &c., it is usual to provide duplicates of all these.

The rougher pieces of apparatus, such as hammers, anvils, the several parts of the heating furnaces, plates for the floors, &c. are run at once from the blast-furnace. On the other hand, the finish, and accuracy of size and shape, which bars, bolts, and in fact, all other descriptions of rolled iron are required to have, demand that the greatest care and attention be paid to the getting up of the rollers. They should be made in the best possible manner, and of the

[1] Foster, *Trans. Nat. Hist. Soc. Newcastle.*

strongest metal, a proper melting furnace being provided, and kept entirely for the purpose. The best coals are indispensably necessary, otherwise the work will be deteriorated by the impurities which it cannot fail to take up when in a highly heated or liquid state. The material ought to consist wholly of No. 1. pigs. A mixture of Staffordshire, Shropshire, and Welsh metal is most suitable.

The best grained rollers for boiler-plates are cast in loam or sand. The mould, which is sunk perpendicularly in the cast-house floor, is capable of containing in an upper part, at least one-third more metal than is necessary to form the roller. The object of this is, to give weight and pressure to the fluid material below, and thereby insure a perfect casting. Without this precaution, the rollers generally turn out honeycombed and unsound. It is also necessary during the running of the metal into the mould, to keep it alive, by constantly stirring it with a stick, the extra metal or head at the same time making up for any deficiencies caused by shrinking or evolution of gas in the interior of the casting. The roller, for whatever purpose it might have been intended, used generally to be cast as a plain cylindrical mass, the grooves being afterwards all cut out by the slow and tedious process of turning. It is now moulded as near as possible to the form which it ought to have when finished, allowing only as much superfluous metal as will admit of its being cleaned up, and brought to a true centre in the lathe. Rollers for boiler-plates and sheet-iron, from the great strain to which they are occasionally subjected, should have the bearing part or neck turned in the shape represented at AA.



The barrel or cylinder should also be slightly concave, because when the slab is first passed through the rollers, it comes in contact only with a small portion of the revolving surfaces. The central parts of the roller thus become highly heated, whilst the extremities are comparatively cool; the consequence is, that the expansion is greatest at the middle, so that, unless this be provided for by concavity in the barrel, the plates become buckled; that is, both warped and uneven in thickness, and consequently unfit for the purposes of the boiler builder. Bar and bolt-rolls are generally slightly case-hardened, this is effected by chilling in a mould or cast-iron case fit for the purpose. That the chilling may not exceed what is necessary, the roller, when cast, is turned out of the case red-hot. This prevents its hardening too much, and allows the turner to finish it with less injury to his turning tools.

We will now enter into a few particulars respecting the sizes of the different kinds of rollers, and the speed at which they are run. Rollers for roughing down are from 4 to 5 feet long, by 18 inches in diameter. The rollers for merchant bars and bolts are generally about 2 feet 6 inches long, 13 inches in diameter, and make about 70 revolutions per minute. With regard to boiler plate and black sheet iron rollers, much depends on the size of the work which they are to perform. They vary in size, from 2 feet 6 inches in length, by 13 inches in diameter, to 5 feet 6 inches in length, by 18 inches in diameter, the speed at which they are run varying from 35 to 40 revolutions per minute. For roughing down small iron, it is usual to run three rollers backwards and forwards; that is, the rollers run in opposite directions. These, and also the finishing rollers for the same descriptions of iron, are generally 10 inches in diameter, and make about 120 revolutions per minute. Guide rollers for small rounds and squares are 8 inches in diameter, and make about 200 revolutions per minute. In all the large works, the rollers vary as to size and also velocity; but the proportions we have here given are those in most general use. Of course, if the rollers are increased or decreased in diameter, the speed must be regulated accordingly. In some of the Staffordshire mills, guide rollers are run so small as 4 inches in diameter, with a speed equal to 400 revolutions per minute. All, except the roughing and boiler-plate rollers, are usually case-hardened. The small rollers, in particular, are fitted up with the greatest accuracy, and carefully chilled. Whilst the speed of rolling thus varies with the size and description of the roller, there is one condition which should be invariable: It is this, that the process ought always to proceed at a certain temperature, so that the particles of the iron may be compressed to the greatest possible degree, and the bar be turned out, with a clean and well-polished skin. For the general purposes of the rolling mill, the engine should be of eighty horse power. In rolling boiler plates, however, where, as was before mentioned, the slab sometimes weighs as much as 10 cwt., a hundred horse power will not be too much. The fly-wheel and shaft, to overcome the great resistance, ought to weigh from 25 to 30 tons. The whole of the boiler plate machinery should be proportionally strong, and detached from the other parts of the mill, so that, when necessary, the whole available power of the engine may be concentrated on the working of these rollers alone. The pinions, if not made of the strongest metal, are liable to almost constant breakage. The connecting spindles ought, if possible, to be made of wrought iron. At some manufactories, the coupling boxes are also made of wrought iron. The shaft of the spur-wheel, and indeed all the other shafts, should be of the same material, the bearings carefully turned, and well case-hardened. Associated with the rolling-mill should be a large and strong lathe of the most improved form and construction, with self-acting slide rests. When the mill is in an active state, this will be almost constantly employed in turning rollers, which, for railway bars and the like, require to be of an endless variety of forms and sizes.

So far the *Forge* has been considered merely as an auxiliary to the rolling mill, being employed to shingle the puddler's blooms preparatory to their passing through the rollers, and being formed into mill-bars. Something further than this seems requisite, in order to a right appreciation of this most valuable piece of machinery in the manufacture of various large and heavy articles required by the engineer. Few of the larger works interest themselves in the manufacture of iron, after it leaves the rolling-mill. This, therefore, forms a separate branch, and is carried on to a great extent in Newcastle-upon-Tyne, Birmingham, Bristol, and several other large towns in the kingdom. It is at establishments in these towns and their neighbourhoods that shafts, cranks, crossheads, and other parts of the steam-engine are forged, and that large chains and mooring anchors are manufactured, not only for the British, but also for the Dutch, Swedish, French, Turkish, Egyptian, and American navies. So low, indeed, is the price at which British iron can be produced, and to so great a degree of perfection has the manufacture of anchors and chains been carried, that these powers pay little more for the latter articles than the cost of Russian or Swedish iron in their own country.

Until forty years ago, it was not attempted to make any work under the forge-hammer exceeding one cwt. We are now indebted to the forge for the manufacture of anchor-shanks, weighing singly from 30 to 45 cwt.; arms for the same, of 18 cwt.; palms, 3 to 4 feet wide, and from 8 to 12 cwt.; steam-engine shafts, 25 feet long, and weighing from 5 to 6 tons.

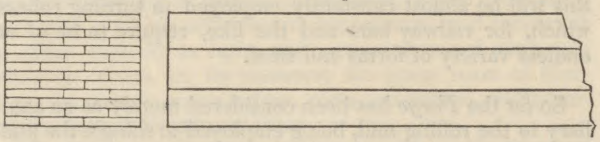
To shew the improvements which have been made in the manufacturing of machinery since 1792, we subjoin a statement of the manual labour attending the making of an anchor for the British Navy at that time and now. In the year 1792, it required 16 men, each working 27 days, to forge and finish an anchor for a first-rate ship in the navy; the anchor when finished weighing 8960 lb.; total number of days, $27 \times 16 = 432$ days. In the year 1835, with the assistance of the forge, the same quantity of work can now be finished in 173 days, making a saving of manual labour by the use of the forge of 259 days.

This statement, along with others which could be given, fully bears out the assertion, that in no part of the manufacture has so much progress been made as in the getting up of anchors and chains. In the year 1808, the sum paid for workmanship on one ton of chains amounted to L. 18; at present chain-cables can be bought for the same sum, including both iron and workmanship.

The "Sovereign of the Seas," built in 1637, carried eleven anchors, one of which weighed 4400 lb., or 39 cwt.; but the largest anchor now made for the navy weighs five tons. Fifty years ago, it was not thought possible to roll bolts and bars; at that time all the boltstaves required for shipping were rounded under the smith's hammer, from Russian and Swedish iron. In the same manner, so little were the uses of the forge understood, that it is only within these very few years that the great and increasing demand for large wrought-iron machinery for steam-boat and railway engines, has led the iron-manufacturer to attempt what had previously been thought impossible.

The forging of large machinery, which is carried on to a great extent at Bedlington, near Morpeth, is sufficiently interesting to claim a particular account in these pages. There the writer of this had the opportunity of seeing the manufacture of a large shaft for the rope-rollers of the Stanhope and Tyne Railway incline engine. It was laid up in a faggot from large flat bars, as shewn in the figure adjoining;

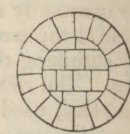
End view. Top view.



a long bar of iron, called a "Porter," being welded into the interior of the mass at one end, for the convenience of moving it about under the hammer. The weight of the iron, previous to being heated, was 7 tons 6 cwt. 1 qr. 26 lb., and the weight of the shaft, when finished at the forge, 5 tons 8 cwt. 2 qrs. 6 lb., shewing a waste in the process of manufacture of 1 ton 17 cwt. 3 qrs. 20 lb., or about one-fourth of the whole. This shaft, which was 25 feet in length, with a cross sectional area of 13 square inches, was probably the largest single piece of iron ever manufactured under a forge hammer. It was finished in eight days. Had it been made under the small hammers, according to the method of working forty years ago, it would have required as many weeks.

Messrs Maudsley and Co. of London have occasionally had shafts forged at these works near five tons in weight; the same manufactory is not less celebrated on another account, namely, as having produced the first rolled malleable iron railway bars. After the shaft has been laid up in the manner described, it is carefully heated in an air furnace, constructed for the purpose, drawn out when ready, as quick as possible, swung upon the anvil, and worked under a very heavy hammer. The better to effect this, it is slung in a cradle working on a screw, which is suspended to a collar, playing over the jib of a strong and powerful crane, capable of sustaining at least twenty tons. This apparatus suffices for the purpose of enabling the forgeman and his assistants with strong iron levers or caul-hooks, to move about and turn round their work as the operation may demand. Sometimes it is urged forwards, at others, by the combined exertions of the workmen, turned over on the anvil, each side in succession being presented to the stroke of the hammer. In this manner it is astonishing to see with what ease and facility the massive shaft is handled during the progress of the heat, which generally lasts about half an hour. At its conclusion the shaft is returned into the furnace, raised afresh to the welding temperature, another heat is taken, and so on until it is finished. It is of the greatest importance that the work be accomplished in so complete a manner, under the forge hammer, that nothing further shall be required of the smith, as the shaft in the process of forging, has acquired a stiffness, which it is desirable that it should retain. After-heating weakens it much, loosening the fibres of the iron, and destroying its elasticity. Notwithstanding all the care of the workman, and repeated heavy hammerings, few shafts are solid to the centre; indeed, it is doubtful if it be possible by any means to obtain a perfectly homogeneous mass where the magnitude is so great.

Large masses of forged and hammered iron almost invariably exhibit a hollowness at or near the central axis. It is difficult to say exactly how this arises, as a curious and important fact, however, it deserves attention. Some time ago it was customary to lay up work of the kind we have been describing with feathered or wedge-shaped bars, as in the attached figure. During the French war, most of the large anchors for the British navy were manufactured in this manner; but many of the shanks of these anchors breaking, it was discovered that only a crust or exterior rim of the shank, exceeding little more than two inches in thickness, was perfectly welded, whilst the bars in the centre, although undergoing the same degree of heat and hammering, were quite loose, and might have been taken out unaltered, at least as to shape.



All the larger pieces of wrought-iron machinery ought to be made under a heavy hammer, capable of being felt to the very centre of the pile of bars, when in a welding state, finished there as far as possible, and then passed into the lathe, planing-machine, or drill, there to be further fashioned to the required shape. If the shaft or other piece of machinery be returned to the fire for a dressing up, it becomes brittle and considerably weakened, the fibre of the iron is destroyed, and the shaft rendered less susceptible of resistance to torsion or twists, that it may be subjected to, in any particular situation; as, for instance, in a steam-boat engine during a heavy sea and hard gale.

It is to be regretted that the iron manufacturer should ever be obliged, as he frequently is, to deteriorate from the quality of a well-forged piece of machinery, for the sake of accomplishing what, with a little more expense, could be as well or better done in the lathe, at the same time without the slightest risk of injury to the iron. When a shaft, which has been fabricated under circumstances of this kind, gives way or breaks, the cause of failure is seldom traced to the right source. The manufacturer is blamed for using a bad quality of iron; the engineer, in nine cases out of ten, little thinking that to his own misplaced economy, or ignorance of the properties and manufacture of iron, is to be attributed, in great part, the misfortune.

Shafts and large machinery are best made from scrap-iron, collected in the dockyards, shops of the large engineers, coach manufactories, and other places where refuse iron accumulates. The scraps, being of various sizes and descriptions, are cut into very small pieces, called nut-iron, blended together, carefully piled upon a flat freestone plate, or, if not convenient, a fire-clay tile, and put in this manner into the balling furnace. The piles heated at once amount from 6 to 8 cwt. After remaining in the furnace about twenty minutes, they are successively taken out with a pair of tongs, thrown under the forge-hammer, and speedily shingled into slabs or blooms. These are again heated in another furnace, and rolled into bars of the shape and size required.

Scrap-iron is the most suitable material for all kinds of engine-work. It also makes the best boiler-plates, rail-bars, &c. Not being so fibrous as the best British iron, it is less liable to split or crack, bears the heat in a large body better, and makes sounder work. Some of the large iron-masters make a description of iron which they denominate scrap-iron. This is manufactured from the crop-ends of the bars, and other refuse collected in the work. It consists, consequently, of all the varieties of quality found in Nos. 1, 2, and 3 iron, the whole being blended together. The result of such a mixture is, the greatest irregularity in quality and texture. The No. 1. or puddled iron in the composition not having undergone the same working as the No. 3, does not unite or coalesce with it; the several parts of the bar have the appearance of being imperfectly welded, and exhibit splits and cracks on the edges.

On the contrary, good scrap-bars, of the description before mentioned, being made from old, and consequently well-worked iron, assume a sound and strong body; and the pieces also of which the bloom is fashioned being small, thrown together indiscriminately, and not piled regularly as the iron from crop-ends, meet together at various angles to each other; the fibres are thereby crossed, and the bar is rendered less subject to that longitudinal lamination so seriously felt in rail-bars, tyres for locomotive-engine wheels, and other similar work.

It is not by any means to be imagined that the advantages of the forge are confined to the putting together of such large masses of iron as have hitherto only been described. In fact, all kinds of edge-tools, agricultural and plantation hoes, sugar-cane bills, axes, adzes, spades, shovels, and the like, are now made with an immense saving of manual labour by the forge; the machinery for this purpose being, of course, lighter in proportion, and the hammer made to work with a greater speed. Nor are the uses of the forge in the manufacture of large articles much more striking than the performances of the rolling-mill in the same department. We have seen large plates, containing as much as thirty-eight square feet of area, engine-beams weighing $11\frac{1}{2}$ cwt. when finished, and 13 cwt. in the slab, respectively formed in the rollers, from a single piece of iron previously prepared beneath the forge-hammer. (C. C. C. C.)

IRONY, in *Rhetoric*, is when a person speaks contrary to his thoughts, in order to add force to his discourse; for which reason Quintilian calls it *diversiloquium*. Thus, when a notorious villain is scornfully complimented with the title of a very honest and excellent person, the character of the person commended, the air of contempt that appears in the speaker, and the exorbitancy of the commendations, sufficiently discover the dissimulation of irony.

Ironical exhortation is a very agreeable kind of trope; which, after having set the inconveniences of a thing in the clearest light, concludes with a feigned encouragement to pursue it. Such is that of Horace, when, having beautifully described the noise and tumults of Rome, he adds ironically,

> Go now, and study tuneful verse at Rome.

IROQUOIS, the name given by the French to the confederacy of North American Indians, called by the English the *five*, and afterwards the *six* nations. They occupied an extensive tract of country near Lake Ontario, and make a considerable figure in the early history of British America. They are now very greatly reduced. Some of the tribes are extinct; others have made considerable advances in civilization; and others, again, have fallen into a state of squalid misery.

IRRADIATION, the act of emitting subtle effluvia, like the rays of the sun, in every direction.

IRREGULAR, something that deviates from the common forms or rules. Thus we say, an irregular fortification, an irregular building, an irregular figure, and the like.

IRREGULAR, in *Grammar*, such inflections of words as vary from the general rules. Thus we say, irregular nouns, irregular verbs, and the like. The distinction of irregular nouns, according to Mr Ruddiman, is into three kinds, viz. variable, defective, and abundant; and that of irregular verbs into anomalous, defective, and abundant.

IRRIGATION.

A HASTY inspection of irrigation and draining would lead to the belief that they are founded on opposite principles. It is seen that draining deprives the land of water, and that irrigation, on the contrary, supplies it with water. It is obvious that the great object of draining, and particularly of furrow-draining, is to present surface water which descends through the upper soil to the retentive substrata below it, with frequent opportunities of egress; and it is also obvious, that the great object of irrigation is to supply the upper soil, the firm foundation on which plants rear their superstructures, as much of surface-water as it can retain, for the purpose of promoting increased vegetation. Notwithstanding this apparent difference in principle between them, both induce similar effects, but the origin of which, lying deeper than the surface of the ground, might easily escape the notice of superficial observers. Both operations, in the first place, are meant to prevent all *stagnation* of water in the upper and under soils; both in fact create *currents* of water in the soil; and these circumstances are of themselves quite adequate to explain the effects of draining and irrigation on the same principle, and for the same purpose,—the promotion of vegetation. It has been found that all plants usually cultivated in agriculture cannot survive in stagnant water, and that in it their places are taken by others of a coarse nature. Now, aqueous meteors are generated in the atmosphere, and afterwards fall on the ground, and reach plants by the absorption of the soil in large quantities, and would stagnate there, were draining not to draw off the superfluous water unnecessary to vegetation in sensible currents, and prevent its stagnation. In like manner, although irrigation presents a copious flow of water to the soil; yet it provides the means of drawing off the redundancy in sensible currents, and preventing stagnation. As draining has the effect of rendering retentive subsoils porous, so irrigation is practised with most effect on porous soils. In short, so dependent are irrigation and draining on each other, that the former acts most beneficially only in conjunction with the latter. Thus the principle which is common to draining and irrigation is the prevention of the stagnation of water; and although of a negative character, it affords sure outlets to the superabundant moisture, and directly promotes vegetation.

The principle on which land is irrigated being thus explained, let us see how it may be made to operate practically, how land is really irrigated. There are four ways of irrigating land with water; and in order to preserve a command over its motions, it must in all cases enter the land to be irrigated at a higher level than where it leaves it.

This disposition of materials is the only way to make water move in a sensible and equable current. 1*st*, One kind of irrigation is called Bed-work Irrigation, which is the most efficient kind by which currents of water can be applied to level ground. 2*d*, Another kind is called Catch-work Irrigation, which is suited to uneven ground. 3*d*, A third gets the name of Subterraneous Irrigation, from the water being supplied upwards to the surface through drains in the subsoil. 4*th*, And the fourth kind is called Warping, when the water is allowed to stand over a level field till it has deposited the mud it contains.

Several particulars require deliberate consideration before determining on forming any kind of water-meadow. The vicinity of a river is a requisite particular, not so much on account of the supply of water, for that may be obtained in winter beside a mountain torrent or a lake, but on account of the fertilizing matter which is generally suspended in the waters of a river. Hence a river, flowing through an alluvial and cultivated country, is preferable to one through a mountainous and rocky country. An ample supply of water is absolutely necessary to beneficial irrigation. It is folly to incur the expense of forming the most perfect water-meadow without an ample supply of water to fill the channels to overflowing. The supply of the water must be on a higher level than the ground to be irrigated. The fall need not be more than is necessary for a pretty rapid current of water, which in ordinary cases may be ten inches or a foot for one hundred or two hundred yards, and about two feet for three hundred yards. The water, if possible, should be taken as far above the meadows as to have a sufficient fall without damming up the river. When this plan is impracticable, but only when impracticable, a dam should be thrown across the stream at such a distance above the meadow, as to secure not only a sufficient fall, but the fields on both sides of the river from inundation, whether the fields belong to different proprietors or not. For, in regard to dams across small streams which form the boundaries of farms or estates, it may not be irrelevant to mention that altercations have frequently arisen from supposed damages arising from inundations or infringements on the rights of waters. In every case, therefore, of constructing a dam for irrigation, it will be wise to avoid the chance of disputes, by acquiring, in the first place, the right for such an erection by purchase or otherwise. When a dam is inevitable, it should be constructed substantially. The first cost will be less than the repairing of a dam which has blown up from under or burst out at the sides. When water cannot be obtained under these pre-requisites, conjoined to an ample supply, then the formation of water-meadows at that place should be altogether relinquished. But should the requisite desiderata be available, the field to be converted into a water meadow should in the first place be thoroughly drained. The most perfect piece of workmanship as a water-meadow will be comparatively useless, unless the water which has passed through the soil to the subsoil find a free egress by drains. Without drains the water will inevitably stagnate on the subsoil, unless indeed the subsoil consists of very porous materials, such as sand, gravel, or fissured rock.

Besides the particulars enumerated, two essential rules in the formation of water-meadows should never be neglected, namely, that no part of them, however small, should be on a dead level; and that every drop of water, while irrigating, should be kept constantly in motion. These rules are founded on the very principle of irrigation which has been illustrated in the prefatory remarks. True inclined planes can be the only form of surface to which these rules will strictly apply; but although it may not be possible to stretch such planes along a great extent of surface, as ground is proverbially uneven, yet every portion of it which is watered directly from the main supply should be so exactly inclined. The spirit-level should be the *vade-mecum* of the irrigator, the eye being deceptive in regard to the levelness of ground; and even with that indispensable instrument, the irrigator will find the formation of a complete water-meadow on an irregular surface no easy task. Superficial observers may see little difficulty in the operation; but the practical irrigator knows how nice a thing it is to adjust irregularities of ground to the constant and equable flow of water. So great is this difficulty, that none but professional irrigators ought to attempt the formation of water-meadows, and they ought to be of established character and experience; for, as Arthur Young wisely remarks, "I should recommend, in the first instance, the employment of a professed irrigator, could the young farmer possess knowledge enough to ascertain the skill of such a man; but I have seen such gross blunders made in Norfolk by such a one, on the farms of four or five persons, and yet highly recommended and coming from Gloucestershire, that I really think a man may just as well trust to himself, with the assistance of books, as put any faith in men who are reputed skilful only in proportion to the ignorance of those who employ them. In the cases to which I allude, the ignorance was unpardonable; for, as they discovered that he drew out all his works without the assistance of a spirit level, they ought to have dismissed him. Not that such a man cannot make improvements, no one can well contrive to bring water on land without improving it; but to pay L. 4 or L. 5, or perhaps more, per acre, for using a small quantity of water to *some* advantage, when the same might be used elsewhere to the *greatest*, is, comparatively speaking, throwing away money."[1]

The first thing to be done for any water meadow is to make the conductor or drain which brings the water from the river to the meadow. The size of the conductor depends entirely on the quantity of water which the meadow requires. Its bottom, at its junction with the river, should always be as low as the bottom of the river, in order to carry away as much mud as possible to the meadows. Its course should be as straight and as near an inclined plane as possible. The stuff taken out of the conductor should be employed in equalizing its banks, or filling up irregularities in the meadow. These general directions naturally lead to the examination of the particulars of which the different kinds of water meadows enumerated consist.

I. BED-WORK IRRIGATION.

This species of irrigation is eminently applicable to level ground, and under it, as the name implies, the ground is thrown into *beds* or *ridges*. After the conductor has been brought from the river to the meadow as directed, it should be led along the highest end or side of the meadow in an inclined plane; and should it terminate in the meadow, and not have to proceed farther on to another, its end should be made to taper when there are no feeders, or to terminate in a feeder. The tapered end will retard the motion of the water, and containing, of course, less water, the water will overflow the banks of the conductor. The main drain to carry off the water after it has irrigated the meadow should next be formed. It should be cut in the lowest part of the ground at the lower end or side of the meadow. Its dimensions should be capable of carrying off the whole water used, so quickly as to prevent the least stagnation, and discharge it into the river. The stuff taken out of it should be used to fill up irregularities in the meadow. In case the river takes a turn along the lower end or side of the meadow, the turn should be used as a main drain to carry off the water, and save the expense of cutting a drain It

[1] *Farmer's Calendar*, p. 295.

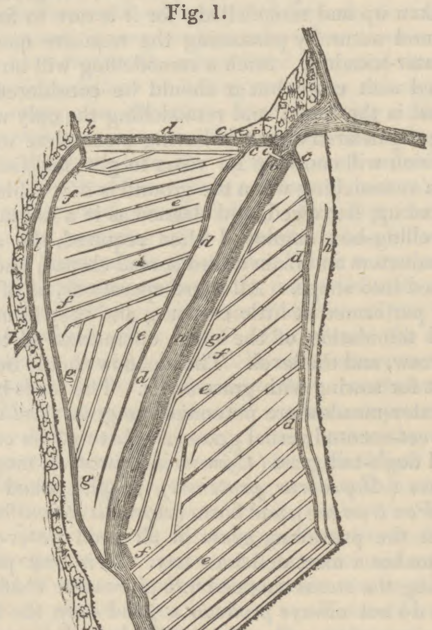
 may be imagined that as a portion of the water will be absorbed by the soil, the main drain need not be made so large as the conductor, merely to carry off the water that has been used; but in practice it will be found, that when the water is muddy, but little of it comparatively will enter the ground, because the sediment, acting as an impervious covering, prevents much of the water from descending into the ground. The next process is the forming of the ground intended for a water-meadow into beds or ridges. That portion of the ground which is to be watered by one conductor should be made into beds to suit the circumstances of that conductor; that is, instead of reducing all the beds over the meadow to one common level, they should be formed to suit the different swells in the ground, and should any of these swells be considerable, it will be necessary to give each side of them its respective conductor. The beds should run at or nearly at right angles to the line of the conductor. The breadth of the beds is regulated by the nature of the soil and the supply of water. Tenacious soils and subsoils, and a small supply of water, require as narrow beds as thirty feet. Porous soils and a large supply of water may have beds of forty feet. The length of the beds is regulated by the supply of water and the fall from the conductor to the main drain. If the beds fall only in one direction longitudinally, their crowns should be made in the middle; but should they fall laterally as well as longitudinally, as is usually the case, then the crowns should be made towards the upper sides, more or less according to the lateral slope of the ground. The crowns should rise a foot above the adjoining furrows. The beds thus formed should slope in an inclined plane from the conductor to the main drain, that the water may flow equably over them. The beds are watered by what are called *feeders*, that is, by channels gradually tapering to the lower extremities, and cut down their crowns, wherever these are placed. The depth of the feeders depends on their width, and the width on their length. A bed two hundred yards in length requires a feeder of twenty inches in width at its junction with the conductor, and it should taper gradually to the extremity, which should be one foot in width. The taper retards the motion of the water, which constantly decreases by overflow as it proceeds, whilst it continues to fill the feeder to the brim. The stuff which comes out of the feeders should be carefully and evenly laid along the sides of the beds. The water overflowing from the feeders down the sides of the beds is received into small drains formed in the furrows between the beds. These small drains discharge themselves into the main drain, and are in every respect the reverse of the feeders; that is, their tapering extremities lie up the slope, and their wide ends open into the main drain, to accelerate the motion of the departing water. The depth of the small drain at the junction is made about as deep as that of the main drain, and it gradually lessens towards the taper to six inches in tenacious and to less in porous soils. The depth of the feeders is the same in relation to the conductor. The stuff obtained from the small drains is employed to fill up inequalities in the meadow. For the more equal distribution of the water over the surface of the beds from the conductor and feeders, small masses, such as stones, solid portions of earth or turf fastened with pins, are placed in them, in order to retard the momentum which the water may have acquired. These *stops*, as they are termed, are generally placed at regular intervals, or rather they should be left where any inequality of the current is observed. Heaps of stones answer very well for stops in the conductor, particularly immediately below the points of junction with the feeders. Solid portions of earth are usually left in the feeders, or tough pieces of turf fastened down with wooden pins; but care must be taken to keep the tops of the pins below the reach of weeds floating on the surface of the water. These stops, however, are nothing but expedients to rectify work imperfectly executed. It must be obvious that a perfectly-formed water-meadow should require few or no stops. The small or main drains require no stops. The descent of the water in the feeders will no doubt necessarily increase in rapidity, but the inclination of the beds, and the tapering of the feeders, should be so adjusted as to counteract the increasing rapidity. At all events *notches* cut into the sides of the feeders to retard the velocity of the water, is much more objectionable than stops, although some writers recommend them; but where they have been observed, the spectator may depend on having seen an imperfect water-meadow. The distribution of the water over the whole-meadow is regulated by the sluice, which should be placed at the origin of every conductor. By means of these sluices any portion of the meadow that is desired can be watered, whilst the rest remains dry; and alternate watering must be adopted when there is a scarcity of water. Each sluice should be placed according to the elevation or depression of the ground which it supplies with water. All the sluices should be substantially built at first with stones and mortar; because a carelessly constructed sluice will permit the leakage of water at all times; and should the water from the leak be permitted to find its way into the meadow, that portion of it will stagnate and produce coarse grasses. In a well formed water-meadow it is as necessary to keep it perfectly dry at one time, as it is to place it under water at another. A small sluice placed in the side of the conductor opposite to the meadow, and at the upper end of it, will serve to drain away the leakage that may haply have escaped from the head sluice. The laying out of the beds, feeders, and small drains, constitutes the nice part of the formation of a water-meadow; it constitutes the test by which the skill of the irrigator is tried; and it is impossible to acquire the skill without practice.

To obtain a complete water-meadow, the ground should be broken up and remodelled; for it is rare to find a piece of ground naturally possessing the requisite qualifications of a water-meadow. Such a remodelling will no doubt be attended with cost; but it should be considered that the first cost is the least; and remodelling the only way of obtaining the desired object of having a complete water-meadow which will continue for years to give satisfaction. To effect a remodelling when the ground is in stubble, let it be ploughed up, harrowed, and cleaned as in a summer fallow; the levelling-box employed when required, the stuff from the conductors and main drains spread abroad, and the beds ploughed into shape. All these operations, as of the farm, can be performed at little expense, and they form the substantial foundation of the nicer operations of the spade, the barrow, and the level. The meadow should be ready by August for sowing with grass-seeds. The seeds best suited for a water-meadow are perennial rye-grass (*Lolium perenne*), sweet-scented vernal grass (*Anthoxanthum odoratum*), crested dog's-tail grass (*Cynosurus cristatus*), meadow foxtail grass (*Alopecurus pratensis*), rough-stalked meadow-grass (*Poa trivialis*), and fiorin (*Agrostis stolonifera*). The fiorin is the prevailing grass in all good water-meadows, and it makes a most delicious hay. It is best propagated by sowing the stems chopped into pieces like chaff. These grasses do not always produce a good crop the first year, but the rye-grass will assist to thicken the crop. Some writers, and particularly Mr Smith in his *Essay on Irrigation*, assert that it is of no importance what grasses are sown in water-meadows, as the most congenial kinds will in time spring up and banish all the others; but is it not better to supply the ground at once with the best grasses than wait for the extirpation of the worst? The method now described of forming a water-meadow is attended with one great disadvantage; the soft ground cannot be irrigated for two or three years after it is sown with grass-seeds.

This disadvantage can only be avoided where the ground is covered with old turf which will bear to be lifted. On ground in that state a water-meadow may be most perfectly formed. Let the turf be taken off with the spade, and laid carefully aside for relaying. Let the stript ground then be neatly formed with the spade and barrow, into beds varying in breadth and shape, according to the nature of the soil, and the dip of the ground; the feeders from the conductor, and the small drains to the main drain being formed at the same time. Then let the turf be laid down again and beaten firm, when the meadow will be complete at once, and ready for irrigation. This is the most beautiful and most expeditious method of making a complete water-meadow, and should always be adopted where practicable, although it should at first be the most expensive.

The water should be let on, and trial made of the work, whenever it is finished; and the motion of the water regulated by the introduction of a stop in the conductors and feeders, where a change in the motion of the current is observed, beginning at the upper end of the meadow. Should the work be finished as directed by August, a good crop of hay may be reaped in the succeeding summer. There are few pieces of land where the natural descent of the ground will not admit of the water being collected a second time, and applied to the irrigation of a second and lower meadow. In such a case the main drain of the watered-meadow may form the conductor of the one to be watered, or a new conductor may be formed by a prolongation of the main drain; but either expedient is only advisable where water is scarce. Where it is plentiful, it is better to supply the second meadow directly from the river, or by a continuation of the first main-conductor. In some instances it may be necessary to carry a conductor over a hollow piece of ground along an aqueduct made for the purpose, called a *carry-bridge*. Such an aqueduct may be made either of wood, cast-iron, or stone and mortar.

Fig. 1.



As a real example of a water-meadow, such as has been described, will illustrate the several particulars specified more accurately than any imaginative case, fig. 1 is a design of one belonging to Mr Loch of Rachan in Peebles-shire, and executed in 1823 by Mr George Stephens, drainer and irrigator, Edinburgh. The design is taken from Mr Stephens' *Practical Irrigator and Drainer*, 1834 (p. 10), a work of great practical utility. The meadow, as may be seen, in fig. 1, lies on both sides of the river Biggar, and contains eight acres, partly of clay, but mostly of gravel, and both resting on a gravelly subsoil. The river supplies the meadow amply with water. The expense of straightening the river, building the dam and sluices, and forming embankments against inundations in every flood, was L. 9 per acre. The work was executed late in spring 1823, and in 1825, four hundred stones of hay per acre were cropped, worth sixpence per stone, or L. 10 per acre, and L. 1 per acre for the aftermath, from land that was not worth L. 2 per acre before being irrigated. The references to the cut are these: *a* is the Biggar water; *b* is the dam 30 inches high across it; *cccc* sluices in conductors; *ddddd* conductors; *eeee* feeders; *ffff* small drains; *ggg* main drains; *h* a drain for cutting off natural springs; *i* a small sluice on the side of the conductor, to carry off any leakage of water from the sluice *c*; *k* a carry-bridge or aqueduct; *ll* conductor to another meadow; .... stops in conductors and feeders.

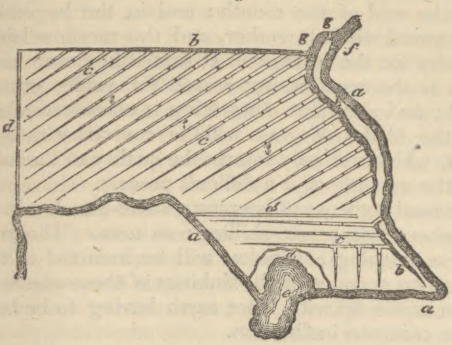
II. CATCH-WORK IRRIGATION.

This kind of irrigation is only applied to sloping banks, and should never be practised where the bed-work system can be introduced, although many are tempted, by the ease and economy of its construction, to prefer it. It is quite different in its construction from the bed-work. Were the feeders placed up and down the slope at right angles to the conductor, as in the case of bed-work irrigation, the water would acquire such a momentum in its descent, as to cut the ground into ruts. No number of stops could prevent this mischief. In order to prevent it, the feeders are cut across the face of the slope in parallel rows below each other. The water overflowing from the upper feeder is caught by the one below it, and so on in succession, till at last it finds its way into a main drain or the river. Main drains are less useful in this kind of irrigation than in the bed-work, as there are no small drains necessary to open into them, the tapering ends of the feeders discharging the water equally over the margin into the river. But it is obvious, that were the feeders on the lower level to receive their whole supply of water from those above them, the sediment in the water would be chiefly deposited by the upper feeders. It is therefore requisite to give a direct communication from the conductor to each feeder. To effect this, the direction of the feeders is made at an acute angle with the conductor, and their distance from each other is regulated by the fall of the ground, and the nature of the subsoil. Where the subsoil is porous, and the fall of the ground one foot in twenty or thirty, the distance between the feeders may be made from twenty to thirty yards; but where the declivity is less, and the subsoil tenacious, the distance should never exceed ten yards. Stops should be placed in the conductor immediately below the points of junction with the feeders; and in the feeders at regular distances, or rather where the current appears to accelerate its motion.

The expense of forming a catch-work meadow may vary from L. 3 to L. 5 per acre. The comparative cheapness of this kind of irrigation, induces many to adopt it in situations which ought to be occupied with bed-work irrigation.

The following design of a catch-work meadow, is taken from Mr Stephens' work above referred to. The meadow was formed by him in 1823, on the estate of Closeburn, in Dumfries-shire, belonging to Mr Stuart Menteith. The references to the cut are these: *aaa*, fig. 2, is the river; *bbb* are conductors; *ccc* feeders; *ddd* main drains, and the river also acts as a main drain; *e* is a lake; *f* the dam across the river; *gg* are sluices in the conductors; .... stops in the conductors and feeders.

Fig. 2.



It may frequently happen that the bed-work and catch-work systems may be beneficially united at the same fall of water. The conductor may be led along the higher ground, and give rise to a system of catch-work irrigation on the sloping ground, and terminate in the bed-work on the more level portion below. Such a compound structure may save much expense in levelling, and will make the most of the water. Instances of this compound-work may be seen at Whitehaugh in Peeblesshire, belonging to Sir John Hay, Bart., and at the Townfoot Meadow of Dolphinton in Lanarkshire, belonging to Mr Richard Mackenzie, writer to the Signet, Edinburgh.

MANAGEMENT OF WATER-MEADOWS.

The formation is not the only difficulty attending water-meadows; their good management is a nice business, and essential to the deriving of benefit from them. It must be confessed that much ignorance and negligence prevail in their management; and when the risk is considered of losing the whole of the fine herbage, and getting coarse in its stead, by bad mangement, a skilful irrigator is a character who ought to be highly appreciated. The particulars which require constant attention are, the state of the water in the river, whether there is sufficient to water the whole, or only a part of the meadow; the regulating of the sluices, so as not to permit more nor less water than the part of the meadow intended to be watered requires; the length of time the water should be allowed to remain on the meadow at different periods of the season; the proper time at which hay harvest and pasturage should commence and terminate; the state and nature of the soil to be irrigated, whether porous or impervious; and the removal of all minute obstructions to the perfect irrigation of the meadow.

Every size of river is not equally suitable for irrigation. A large flowing stream, supplying sufficient water at all times, affords facilities for irrigating a part or the whole of a meadow, much better than a brook which swells and falls with every shower of rain. At the same time whatever may be the command of water, it is an error to attempt to irrigate too large a surface at one time. The attempt to force a larger quantity of water than the feeders and drains can easily convey, will end in deluging one part, whilst another will be stinted; and where there is inequality of irrigation, there will be inequality in the quantity and quality of the grass. Where there is an ample supply of water, therefore, no more ground should be irrigated at one time than can be covered equally to the requisite depth by the natural force of the water. Where the supply is short of this, which is more frequently the case, the water should only have as much ground allotted to it as it can effectually irrigate. The intervals between the irrigations will be greater when the supply of water is scanty than when plentiful; but notwithstanding this, the effects produced on the meadow in both cases may be nearly equal, according as the weather is favourable or otherwise. The adjustment of the water by the sluices is a delicate operation under every circumstance, but particularly so when there is at times a deficiency of water. The falling or rising of the water in the river requires particular attention, and the changing of the water from one part of the meadow to another, or even from one bed to another, according to its abundance or deficiency, particular dexterity. Attention to the sluices for a short time every day, will obviate many risks of bad management. A great error may be committed by permitting the water to remain too long on the ground at a time. Unless the ground gets the air and becomes dry at stated periods, the finer grasses will be destroyed, and those of coarse quality will spring up. The watering may be continued for as long as fifteen days in the beginning of the irrigating season in November, but the time should be gradually lessened till March or April, when it should cease altogether. Between the intervals of watering, the land should be laid completely dry. Precautions are particularly necessary in letting the water off and on in frosty weather, frost taking quick hold of wet grass land, and throwing the plants out by the roots. The water should be let off on the morning of a dry day, and the land thus becoming dry in the course of the day, the frost will not injure the grass at night. Or, what is a still safer method, the water should be taken off in the morning and put on again at night, but few persons will take the trouble of attending so minutely to irrigation. In spring the new grown tender grass will be easily destroyed by frost, if the utmost attention be not paid to the state of the ground, either by protecting it with water, which is the surest protection it can receive, or making the ground thoroughly dry in dry weather, for dry cold never injures even young grass. There is another error which should be guarded against: when water remains too long on the ground in the spring, it generates a white scum, of the consistence of melted glue, which, when left on the grass, inevitably destroys it. Instances may be observed of water being permitted to remain on meadows from the autumn till eight or ten days before the cutting of hay. The consequences are, that the hay is of the coarsest quality, and the early bite for sheep entirely lost. It seems to be a judicious recommendation to depasture the early grass on water-meadows with ewes and lambs in March and April, and to eat it barely down before May with a heavy stock. After that the grass is allowed to stand for hay; but some recommend that it should be irrigated for a week, or a few days, to clean the pasture; whilst others think the irrigation unnecessary, and even dangerous, where sheep are kept, by tainting them with rot on the aftermath. There is no doubt that grass after being irrigated in summer, will affect sheep with rot; but whether that which has been irrigated in May, before the hay has been cut down, will so affect them on the aftermath, is not so decidedly known. At all events it is well known that the purest water allowed to irrigate land too long at any time, but particularly in spring or summer, deposites a substance which cannot be called a sediment, nor, judging by the eye, can it even be called an impurity. It is a very fine transparent colouring on the grass, nearly resembling the fine cobwebs which float through the air in a beautiful day in autumn. From its bad effects on sheep it was observed by our forefathers, and known to them by the name of *lace*. It may occasionally be observed on the sides of mountains near wells, having a sparkling appearance. This *lace* is a rapid promoter of rot in sheep.

When it is determined to irrigate, the drains and feeders should be previously inspected, all obstructions removed, and dilapidations amended. Whatever difference of opinion may exist on irrigating at this particular period of the season, all irrigators are agreed that early irrigation in autumn produces greater effects than late, and that water should be used largely during the winter, and scantily during the spring. It is possible that the benefits derived from early irrigation, especially after rains, may arise from the good effects of manure of various kinds, accumulated on the land during summer, being washed down by the rains, and mixed with the irrigating water; and it is certain that abundant irrigation in winter protects the grass from cold, as the temperature of grass under water in winter is seldom under 40° Fahrenheit. The signs of early and luxuriant vegetation observable on water-meadows in spring, when the rest of the ground may be covered with snow, evince the protective power of water. After the hay is carried off, the water is sometimes let on, to promote the growth of the aftermath, which it will no doubt do; but the rank grass encouraged by this summer irrigation will undoubtedly rot sheep. Where sheep are kept, and intended to depasture meadows, there should be no irrigation in summer. Cattle are not affected as sheep.

Should the irrigation be postponed till the autumn, in the beginning of October, the first duty of the irrigator is to see that all the feeders and drains are cleared of every obstruction, occasioned by the treading of sheep or cattle. The sluice is then drawn up, and if the water be abundant, the conductor and feeders will be filled with water in about half-an-hour. The motion of the water should first be adjusted in all the conductors; then in the feeders nearest the upper part of the meadow, and then in the lower ones in succession. The sluices regulate the water in the conductors, and the position of the stops regulates the water in the feeders. The stops should be so placed, as to cause the water to overflow the sides of the feeders, by making the openings at the sides of the stops wider or narrower. This first general inundation will shew any irregularities on the surface of the meadow; and that some irregularities will exist in the best-constructed water-meadows, it is not in the power of art to prevent. The earth in the filled-up hollows will subside, whilst the hard portions of ground which have been reduced will maintain their new shape. The irregularities should now be marked and rectified in the ensuing summer. At least three such adjustments of the water are necessary, before an irrigator should be satisfied that the meadow is properly irrigated with the requisite depth of one inch of water. This quantity of water should be continued over the meadow during October, November, December, and January, from fifteen to twenty days in succession, according as the weather is fresh or frosty, wet or dry. Between every such interval, the meadow should be laid thoroughly dry for five or six days, to give the grass air; and should the weather threaten a lengthened period of hard frost, the watering should be entirely discontinued for the time; for in thawing, the sheet of ice which covers the surface of the meadow will draw every plant of grass out by the roots, and make the soil like a mass of fermented dough. During the period of irrigation, the meadows should be regularly visited and inspected once in every three or four days, to correct any deviation from regular watering, such as may arise from collections of weeds, petty depredations of men and beasts, sticks, stones, or leaves, that may have fallen in and been detained in the conductors and feeders.

In February, great attention is required from the irrigator, as the grass will now begin to vegetate. The periods of watering must be shortened, and those of drying must be proportionally lengthened. White scum, frost, and such like evils, should be carefully avoided, as the tender grass will sensibly feel their injurious effects.

In March, the same precautions are requisite; but in the south of England, where grass is sufficiently abundant for stock in this month, the irrigation should be dispensed with. In Scotland, irrigation may be continued all April, but with such caution, that the water should be allowed to run only five or six days at a time, and gradually lessened towards the end of the month; and in the beginning of May dispensed with altogether, and the meadow laid thoroughly dry for the summer. It should be borne in mind, that this is the most trying season for young grasses in Scotland; and also, that if watering is continued after this month, the blades of grass will be covered with a gritty sediment, which not only injures the quality of the hay, but renders the mowing of it a difficult process.

The annual expense of keeping a water-meadow in repair may be about five or six shillings an acre. The greatest expense in keeping a meadow will be incurred in the second year, on account of the sinkings of those places which had been made up with loose earth having to be brought up to the common inclination.

III. SUBTERRANEOUS IRRIGATION.

This species of irrigation is so named, because the supply of water is derived from under the surface of the ground to the upper soil. It is only applicable to perfectly level ground, so raised above the supplying river, as to admit of a complete drainage of the field to be irrigated. This system of irrigation consists, in the first place, of ditches being formed around all the sides of the field. These act the part of conductors when the field is to be flooded, and of main drains when it is to be laid dry. The water flows from the ditches as conductors into built drains or conduits, formed at right-angles to them, in parallel lines through the fields, and it rises upwards in them as high as the surface of the ground, and again subsides through the soil and the conduits into the ditches as main drains, and thence into the river. Sluices are requisite to convey the water from the river into the ditches. This submersion, as it may be called, rather than overflow, of the ground in water, must be conducted with great care, and the water let on very calmly; for were the water let on or taken off with a forcible current, the finer particles of the soil would be detached, and carried off into the river. Indeed, however carefully the operation may be conducted, the only advantage derived from this species of irrigation is the moistening of dry ground in dry weather, which would otherwise be parched up; and in this respect the operation is best conducted in summer, and is as applicable to arable as to pasture land. It can therefore be of no importance to subterraneous irrigation, whether the water be clear or turbid, since all the sediment must be seethed through the soil, before it can possibly reach the surface of the ground.

IV. WARPING.

Warping is the overflowing of level ground with salt water within tide mark. Of course, it can only be practised near the sea, and most frequently it is attempted within the estuaries of large rivers, which have flowed through alluvial cultivated countries. Its immediate effect, which is highly beneficial, is the deposition of silt from the tide. To insure this deposition, it is necessary to surround the field to be warped with a strong embankment, in order to retain the water as the tide recedes. The water is admitted by valved sluices, which open as the tide flows into the field, and shut by the pressure of the confined water when the tide recedes. These sluices are placed on as low a level as possible, to permit the most turbid water at the bottom of the tide to pass through a channel in the base of the embankment. The silt deposited after warping is exceedingly rich, and capable of carrying any species of crop. It may be admitted in so small a quantity as only to act as a manure to arable soil, or in such a large quantity as to form a new soil. This latter acquisition is the principal object of warping, and it excites astonishment to witness how soon a new soil may be formed. From June to September, a soil of three feet in depth may be formed under favourable circumstances. These circumstances are summer, and the very driest season and longest drought. In winter and in floods warping ceases to be beneficial. In ordinary circumstances, a soil from six to sixteen inches in depth may be obtained, and inequalities of three feet filled up. But every tide generally leaves only one-eighth of an inch of silt, and the field which has only one sluicc can only be warped every other tide. The silt, as deposited in each tide, does not mix into a uniform mass, but remains in distinct layers. The water should be made to run completely off, and the ditches should become dry, before the influx of the next tide, otherwise the silt will not incrust, and the tide not have the same effect. Warp soil is of surpassing fertility. The expense of forming canals, embankments, and sluices for warping land, is, on an average, about L. 10 an acre. A sluice of six feet in height, and eight feet wide, will warp from sixty to eighty acres, according to the distance of the field from the river. The embankments may be from three to seven feet in height, as the field may stand in regard to the level of the highest tides.

V. FLOODING.

Flooding land on the margins of lakes may be considered as a specics of irrigation or warping. A successful attempt of this kind may be seen on the margin of Loch Ken, in Kirkcudbright, where 240 acres can be flooded at pleasure, when the water of the lake is in a favourable state.

In Great Britain, irrigation is practised to the greatest extent in Gloucestershire, Wiltshire, and Drumfriesshire, and partially in some other counties. In England it has long been successfully practised. Into Scotland it is comparatively of recent introduction. The estates of the Duke of Buccleuch on the Esk, Ewes, Yarrow, and Ettrick rivers, first enjoyed the benefits of irrigation to any extent in Scotland; but it is painful to observe that those water-meadows have fallen into decay from inattention. The land is now in a worse condition than if it had never been irrigated, because the very means which were used to direct the water to the land for beneficial irrigation, now form receptacles in which surface-water stagnates. Many of these meadows have since been broken up for corn culture, the high pricc of corn during the war having tempted their destruction. Now that live-stock remunerates the farmer better than corn, the rash step of destroying them has no doubt been by this time sincerely repented of. The water-meadows belonging to Mr Menteith of Closeburn, in Dumfriesshire, were formed about the same time, but having, since their formation, been carefully attended to, they continue to yield abundantly.

Warping is only practised in Lincolnshire and Yorkshire, in the estuary of the Humber, in the rivers Trent, Ouse, and Dun, which flow into it. The silt is an extraordinary substance. It seems to be doubted whence it comes. The Humber is clear at its mouth, and none of the rivers which flow into it bring the silt down in the floods. On the contrary, the floods invariably injure its quality, which is in the highest perfcction in the driest summers. Apparently it is a mixture of sand and clay, for it cakes on drying, and will cleanse cloth of grease like fuller's earth; and its arenaceous property is quite obvious; but its analysis by a chemist many years ago afforded no clay, the principal ingredients being a fine sand, a considerable portion of lime, some mica, and a minute portion of saline matter. It would be desirable to have a correct analysis, by some eminent chemist of the present day, of this remarkable substance.

Subterraneous irrigation is chiefly practised in drained morasses, which are apt to become too dry in summer, by closing up the mouths of the main drains, and causing the water in them to stand back in all the drains till it rises up to the soil. It was recommended by the late celebrated engineer Mr Rennie, to be practised on some extensive fens which he had drained in Lincolnshire, near Boston. To irrigate effectually in this manner, it is necessary to build the mouths of the main drains with strong masonry, and erect sluices for the retention of the water in the drains. This species of irrigation may also be attempted on any flat piece of ground resting on a gravelly bottom, by means of ditches which surround it, and which can command water from a lake or river. Turnips or potatoes, or any kind of crop, whether drilled or not, might be beneficially watered in this manner in a dry summer.

ADVANTAGES OF WATER-MEADOWS AND WARPING.

The advantages derived from water-meadows and warping, as stated by authors who have written on those subjects, almost exceed credibility. One author of some standing says:—"Having heard that the proprietor of an old floated meadow at South Cerney (in Gloucestershire), had disposed of the produce of it, in the year 1795, in a way well calculated to ascertain its real value, I wrote to a person who resides on the spot, requesting him to send me a particular account of the product, and I received the following statement.—In ordcr to make the most of the spring feed, the proprietor kept the grass untouched *till the 2d day of April*, from which time he let it to the neighbouring farmers, *to be eaten off in five weeks* (*which ran a week into May*), by the undermentioned stock, at the following rates per head, viz. a sheep tenpence per week; a cow three shillings and sixpence; a colt four shillings. The quantity of land is eight acres.

107 wether sheep one week, . .	L. 4	9	2
8 cows do.	1	8	0
4 colts do.	0	16	0
	L. 6	13	2
Which for five weeks amount to .	L. 33	5	10
Add three colts for three weeks, . .	1	16	0
Equal to L. 4 : 7 : 8 per acre,	L. 35	1	10
The hay crop was, as usual, about fifteen tons, and was five weeks in growing.			
15 tons, suppose at 50s. per ton, . .	37	10	0
Afternıath, 15s. per acre, . . .	6	0	0
Total, equal to L. 9 : 16 : 5 per acre,[1]	L. 78	11	10

The L. 4 : 7 : 8 were made at a time when other grass-lands are in a dormant state, or exhibit but feeble symptoms of vegetation. But the reader will perhaps see the advantages of this art in a still stronger light, when he is told that this meadow, which is now in the occupation of a miller, was a few years ago in the hands of a farmer, who, being at variance with the miller, was entirely deprived of the use of the water for a whole winter, which, unfortunately, was succeeded by a very dry spring and summer; of course the spring feed was lost; and the whole hay crop of eight acres was only three tons."[1]

In 1802, Mr Smith laid out a water-meadow on the Pais-

[1] Wright *on Irrigation*.

Irrigation. ley farm, near Woburn, Bedfordshire, for the Duke of Bedford, and in 1803 its produce was as follows:—

In March, 240 sheep for three weeks, at 6d. each per week, ...	L.18 0 0
In June, mowed 18 tons hay, at L.4 per ton,	72 0 0
In August, mowed 13½ do. do.	54 0 0
In September, eighty fat sheep for three weeks, at 4d. each per week, . . .	4 0 0
It then fed lean bullocks, the feeding not valued, equal to L.16 : 13 : 8 per acre,[1]	L.148 0 0

These two cases may suffice as examples of successful irrigation in England. The following cases occur in Scotland, a country, from its irregularity of surface, not naturally suited to that species of improvement. Nevertheless, in all the pastoral districts, both in the north and south, an abundance of early food in spring for ewes and lambs might be obtained, by judicious irrigation, in every valley which contains a river. In mountainous districts, the rivers may not supply the richest quality of water for irrigation, but there the soil on the margins of rivers being generally of friable loam, would be peculiarly benefited by irrigation. Such land is invariably sound for sheep when drained; and if made dry, and then irrigated, it would, early in spring, and indeed throughout the summer, afford the finest quality of the richest herbage. Water-meadows in such situations could be inclosed by themselves, and they could supply hay, if required, for the sheep-stock in winter, or be pastured at pleasure by any kind of stock during the summer.

To begin with an instance of simple irrigation in a pastoral district. "Fallaw Meadow, on a large sheep-farm belonging to Sir George Montgomery, Bart. of Macbiehill, in Peeblesshire, containing fifteen acres, was inclosed from moorland in 1816; and by collecting the water from the surrounding sheep-drains, five acres are partially irrigated, and the remaining ten are top-dressed with the manure made from part of the produce which is consumed in winter by the sheep of the farm, in a wooden shed near the meadow. By this simple method of improvement, fifteen acres of common sheep-pasture land give the proprietor from three thousand five hundred to four thousand stones of hay per annum, averaging sixpence per stone. What an immense advantage to a sheep-farm! By this simple process of inclosing, and cutting a few small feeders and drains, the owner is enabled to provide food for his flock, when his less fortunate neighbours' sheep must either starve or be supplied from the farm-yard; but I am afraid there are very few sheep-farmers who are so fortunate as to have any hay beyond what is requisite for stock at home. Sir George fed the same number of sheep on the farm as he did before the meadow was taken off and inclosed; and I am fully persuaded that the same improvement might be made on almost every sheep-farm in Tweeddale, for in almost all of them, there are situations where fourteen or fifteen acres might be inclosed and partially irrigated, as in every pastoral district there are numerous rills which might be easily collected and used to the greatest advantage, at a very trifling expense; so that, instead of being obliged, in snow-storms, to send fifty thousand sheep to a milder climate in the southern parts of Dumfriesshire (where owners are obliged to be at the mercy of their southern neighbours, not to mention the very serious injury the flocks receive by long and fatiguing journeys), by adopting the above system of improvement a considerable part of the losses generally sustained every year would be prevented."[2]

Here is an instance of the conversion of peat-bog of little value into a water-meadow of great value. "Sir Thomas Gibson Carmichael, Bart. of Castle Craig, commenced, Irrigation. in the year 1817, by forming five acres with the plough and spade into regular bed-work. The land, in its natural state, was a complete bog, valued at eight shillings of yearly rent per acre. The formation was difficult, on account of the great number of deep peat-holes which were obliged to be filled up, to bring the surface to a proper level. The expense of levelling and forming the beds was L.6 per acre, the crop of hay was 466 stones of 22 lb. per stone per acre, valued at fivepence per stone, and the after-grass at 18s. per acre, making L.10 : 12 : 2 per acre of gross produce."[3]

But the greatest promoter of irrigation in Scotland is Mr Stuart Menteith of Closeburn, in Dumfriesshire. His water-meadows comprehend both mossy and good soil. They extend to about two hundred acres, and are connected with reservoirs for containing water which can flood two hundred acres more. In his estate in Ayrshire, on the river Nith, Mr Menteith intends to form two hundred acres more of water-meadows. As a proof of the possibility of improving good land by irrigation, the catch-work meadow, represented by fig. 2, containing twenty-five acres, is a remarkable and satisfactory instance of Mr Menteith's operations. "The land of this meadow, before being watered, was worth L 3, 10s. per acre, the expense of levelling and formation L.5 per acre. The produce of 1824 was as follows:—

200 ewes and lambs for seven weeks, at 5d. each per week, ...	L.29 3 4
300 stones of hay per acre, at 8d. per stone,	250 0 0
Aftermath, at 20s. per acre, ...	25 0 0
	L.304 3 4

Being L.12 : 3 : 4 per acre. The quality of the hay was equal to that of any clover-hay in the kingdom."[4]

Another instance only, among many which exist in Scotland, shall be given of the advantages derived from common irrigation, and that is, of the bed-work water-meadow belonging to Mr Loch of Rachan, in Peeblesshire, and forming the subject of the first figure illustrating this paper. "It was formed late in the spring of 1823; the crop of hay in 1825 was judged by the neighbours to be upwards of 400 stones per acre, worth sixpence per stone, and the aftermath at L.1 per acre, making the gross produce worth L.11 per acre, instead of L.2, at which the land was valued before being irrigated."[5]

But this enumeration of the several cases of successful irrigation would be incomplete, were the water-meadows in the neighbourhood of Edinburgh omitted to be particularized. The city of Edinburgh stands on an eminence, which commands the cultivated country around it. Commanding as the situation is, water from the Crawley Spring, in the Pentland Hills, situate at seven miles distance, flows to the top of every house in the city. A ready means is thus provided of washing away all the filth of the houses and streets, which is conveyed in large sewers to the lower end of the town, where their contents are made to irrigate many acres of naturally rich and also of poor soil. Probably upwards of 200 acres are thus irrigated for the production of grass for the cowfeeders who supply milk to the inhabitants. The rent for which these meadows are let in small portions to cowfeeders varies on an average from L.20 to L.30 per acre. Some of the richest meadows were let in 1835 at L.38 per acre; and in that season of scarce forage, 1826, L.57 an acre were obtained for the same meadows. The largest proprietor of these meadows is Mr Miller of Craigintinny, who possesses about one hundred and thirty acres; part of them, comprising land

[1] Smith's *Essay on Irrigation.* [2] Stephens' *Practical Irrigator.* [3] *Ibid.* [4] *Ibid.* [5] *Ibid.*

now of the richest quality, having been thus watered for nearly a century, and part of them of the poorest sandy soil. The waste land called the Figget Whins, containing thirty acres, and ten acres of poor sandy soil adjoining them, were formed into water-meadows in 1821, at an expense of L.1000. The pasture of the Figget Whins used to be let for L.40 a-year, and that of the ten acres at L.60. Now the same ground, as meadows, lets for L.15 or L.20 an acre a-year, and will probably let for more as the land becomes more and more enriched. It is stated by Mr Stephens,[1] that one hundred and ten acres of Mr Miller's meadows, in 1827, yielded a clear profit of L.2300. The repair of these meadows costs from ten to fifteen shillings per acre, which is comparatively a large sum for repairs, but then they are not only watered during the winter, but for two or three days between the intervals of cutting the grass during the summer. The grass is cut from April to November, every three, four, or five weeks, according to the richness of the vegetation. It is exceedingly tender and succulent, and suitable to the production of a large quantity of milk; and were it not frequently cut, it would lie down, and soon rot at the roots.

After these striking instances of the advantages which are derivable from irrigation in a pecuniary point of view, by largely increasing the rent of land, must be mentioned the advantages which are derived from a large increase in the produce of the soil. The early grass in March, which could only be fostered by irrigation, is of the most essential use to ewes and lambs, and it offers an excellent substitute for the artificial grasses, which are usually obliged to be heavily stocked in early spring, when they are unable to bear it; and in truly pastoral districts, where artificial grasses are cultivated to a limited extent, and where old grass is generally long in springing, the breeding stock of sheep is apt to suffer in spring; but an irrigated meadow would not only supply early and abundant food, but it would enable the store-masters to raise an early crop of lambs. The large crop of fine hay which is subsequently cut from water-meadows after the pasturage of the early grass, also insures the safety of the flock, and the growing condition of the herd, in the severest winter; whilst it at the same time supplies the manure which fertilizes, to an increasing extent, the land kept under arable culture. Whether, therefore, in pastoral districts, or in the neighbourhood of large towns, or wherever an abundant supply of river water through an alluvial cultivated country can be obtained, irrigation will certainly repay, in a short time, all the expense and trouble which are necessary for its preparation.

The advantages of warping are thus described, in a particular instance, by Arthur Young:[2] "Mr Webster, Bankside, has made so great an improvement by warping, that it merits particular attention. His farm of 212 acres is all warped, and to show the immense importance of the improvement, it would be necessary only to mention that he gave L.11 an acre for the land, and would not now (1805) take L.70 an acre; but he thinks it worth L.80, and some even L.100; not that it would sell so high at present; yet his whole expenses of sluices, cuts, banks, &c. did not exceed L.2500, or L.12 an acre. Take it at L.12, and add L.11, the purchase money, together L.23 an acre; if he can sell it at L.70, it is L.47 per acre profit. This is prodigious, and sufficient to prove that warping exceeds all other improvements. He began only four years ago. He has warped to various depths eighteen inches, two feet, two and a half feet, &c. He has some, that before warping was moorland, worth only one shilling and sixpence per acre, now as good as the best. Some of it would let at L.5 for flax or potatoes, and the whole at fifty shillings. He has twenty acres that he warped three feet deep between the beginning of June and the end of September, and eighteen acres, part of which is three feet and a half deep. He has applied it on stubbles by way of manuring, for it should be noted, as a vast advantage in this species of improvement, that it is renewable at any time; were it possible to wear out by cropping or ill management, a few tides will at any time restore it. As to the crops he has had, they have been very great indeed; of potatoes from 80 to 130 tubs of 36 gallons, selling, the round sorts, at three shillings to three shillings and sixpence a tub, and kidneys at five to eight shillings. Twenty acres warped in 1794, could not be ploughed for oats in 1795, he therefore sowed the oats on the fresh warp, and scuffled in the seed by men drawing a scuffler, eight to draw and one to hold; the whole crop was very great, but on three acres of it, measured separately, they amounted to fourteen quarters one sack per acre. I little thought of finding exactly the husbandry of the Nile in England. I had before heard of clover-seed being sown in this manner on fresh warp, and succeeding greatly. He warped twelve acres of wheat stubble, and sowed oats in April, which produced twelve quarters an acre. Then wheat thirty-six bushels an acre. His wheat is never less than thirty. Six acres of beans produced thirty loads per acre, or ninety bushels; one acre, measured to decide a wager, yielded ninety-nine bushels; has had 144 pods from one bean on four stalks; and Tartarian oats seven feet high. One piece warped in 1793, produced oats in 1794, six quarters an acre; white clover and hay-seeds were sown with them, mown twice the first year; the first cutting yielded three tons of hay an acre; the second one ton, and afterwards an immense eddish. Flax forty to fifty stones per acre. Warping, it seems, brings weeds never before seen, particularly mustard, and cresses, wild celery, with plenty of docks and thistles."

It is seen, from this statement of Mr Young, that the advantages of warping are very great; and surely so important an improvement ought not to be neglected when it can be put into practice. It is much superior in its effects to irrigation with common water, the mud creating a new soil, and not merely amending an old one. What the land intended to be warped may be, is not of the smallest consequence; a bog, clay, sand, peat, is all one, as the warp raises a soil in one summer of six to eighteen inches thick, and fills up every inequality.

Warped land at first being raw and cold, requires particular treatment. Corn is not the best crop after warping. Oats, it has been seen, may succeed, barley is never attempted, and wheat is not advisable, but sown grass-seeds thrive most luxuriantly. It is good husbandry, therefore, to sow warp with grass-seeds, and let them remain for at least two years; after them wheat will succeed, then beans, and then wheat again, but never barley on any consideration. All the green crops succeed well. In some instances, warp may contain as much salt as to hurt vegetation, in which case an exposure to the air in summer is necessary to neutralize its pernicious action on vegetation.

The quality of the water is an important element in the process of irrigation. It has been alleged that whether water is clear or turbid, irrigation is of service to grass land. There is much truth in this allegation; but it does not declare the whole truth. No doubt moisture alone is of great service to the vegetation of grass on sandy soils in a dry season; but a deposition of mud along with the moisture would surely not benefit the grass the less, nor would it injure the bare soil.

The waters of the Nile and Ganges would alone promote vegetation on their banks, the soils of which seldom expe-

[1] Stephens' *Practical Irrigator*, p. 77.

[2] *Farmer's Calendar*, p. 387.

rience the refreshing sustenance of rain; but the inundations of those mighty rivers would not be hailed with ecstasy and gratitude on the return of every season, were their waters devoid of the fertilizing mud with which they are largely impregnated. Major Rennell states that the Ganges contains a two-hundredth part of its volume of mud, and that it thus carries 2,509,056,000 cubic feet of it per hour. In like manner, the Nile contains a hundred and twentieth part of its bulk in mud, or 14,784,000 cubic feet of it per hour. It is impossible but that the water of all rivers contains at all times, even when purest, some sediment; but it is obvious that those rivers which flow through cultivated countries must contain at all times the greatest quantity of sediment. In this way the rivers of plains must contain more mud than the rivers of mountains; and hence irrigation exhibits the most favourable results in the plains. But were no other proof of the superiority of turbid over clear water for irrigation to be found, the luxuriant produce of the water-meadows in the neighbourhood of Edinburgh, which are watered from the common sewers of that city, would of itself supply a convincing illustration.

Similar results could *never* be derived from clear water; nor is *it ever* found so superabundantly rich as to be necessary to be treated like the water of those meadows next the town, where holes are dug in the ground, for the purpose of catching the grosser materials with which it is charged, before it is used for irrigation.

VI. HISTORY OF IRRIGATION.

Irrigation is at least coeval in antiquity with embanking and draining. It is probably of greater antiquity. Nature had, no doubt, first taught man the art of irrigation by the inundations of rivers; but nature could teach neither embanking nor draining. Egypt was the field which was first artificially irrigated. There the fertilizing effects of the water of the Nile, after its overflow, could not fail to attract the attention of its inhabitants, and teach a simple lesson to the Egyptians, who had only to imitate nature, to secure the fertility of the soil lying beyond the reach of the inundations of the Nile. The remains of canals as capacious as the beds of rivers, which are still to be seen in that sand-desolated country, evince the gigantic efforts which had at one time been made by its inhabitants to irrigate that portion of their country upon which a drop of rain never falls to refresh its languishing vegetation. These canals traverse the whole country, and are so directed as probably to have been made to receive the water of the Nile, and conduct it to every part, to the top of the rising grounds as well as to the bottom of the hollows; the inequalities of hill and dale not being great in Egypt. The large lakes of Mœris, Behire, and Mareotis, all probably artificial excavations, had perhaps once formed extensive reservoirs to supply the canals, after the Nile had retired within its own banks. At what time all these mighty contrivances were begun, history is as silent as on the origin of the pyramids. It is, however, related that Sesostris greatly increased the number of the canals, which must have been at a period of great antiquity, for he reigned about the sixteenth century before the Christian era. Greater efforts to promote irrigation were more urgent in Egypt than in most other countries; for no rain fell in that country to cherish vegetation; and rice forming the chief food of its inhabitants, it could not be raised without a great supply of water.

It is therefore highly probable that the remains of great canals and lakes are indicative of the majestic scale with which the Egyptians had prosecuted the art of irrigation. It is, however, prudent to speak with caution on matters connected with the agriculture of ancient Egypt; for our knowledge of its husbandry is chiefly derived from hints contained in Scripture history, and not from its own historical records. The historian of Egypt, Herodotus, was a Greek, and lived at so late a period as the fifth century before the Christian era, long after the glory of Egypt had departed; whereas the Scriptures supply us with facts of Egyptian agriculture of much greater antiquity, isolated though they certainly are. Such circumstances as the following indicate the existence of irrigation in Egypt at a very remote period of the world. When Abraham and Lot journeyed together in search of a country to abide in after they had left Egypt, they agreed to separate, when they found that the land they were then in could not supply sufficient food for their united flocks and herds; and we are told that Lot chose the plain of Jordan, because it was watered as well as the land of Egypt. "And Lot lifted up his eyes and beheld all the plain of Jordan as thou comest into Zoar, that it was well watered every where, before the Lord destroyed Sodom and Gomorrah, even as the garden of the Lord, like the land of Egypt."[1] Egypt never contained rivers to water it, there being only the Nile; so that the similitude between "the plain of Jordan" and "the land of Egypt," to the mind of Lot, must have arisen from the rivers in Jordan being as numerous as the canals in Egypt; and Lot having witnessed the fertilizing powers of the water of these canals in Egypt, naturally supposed that the rivers would produce a similar effect on the plain of Jordan. The Egyptians had been in the habit of watering their gardens as well as their fields, and this they accomplished at pleasure, by raising water with a machine which they worked with the foot. Simple as such contrivances were, and they are to be seen in Egypt at this day, they could not fail to be troublesome. Dr Clarke describes the Egyptians, when raising water for their gardens, as requiring to work stark naked, or only partially covered with a blue striped shirt. When Moses, therefore, described the promised land to the Israelites, he represented it as a land which was supplied with water in a natural manner, in contradistinction to the more difficult and artificial way by the foot in Egypt: "For the land whither thou goest to possess it, is not as the land of Egypt from whence thou camest out, where thou sowedst thy seed and wateredst it with thy foot, as a garden of herbs: But the land whither ye go to possess it, is a land of hills and valleys, and drinketh water of the rain of Heaven: And it shall come to pass, if ye shall hearken diligently unto my commandment which I command you this day, that I will give you the rain of your land in due season, the first rain and the latter rain, that thou mayest gather in thy corn, and thy wine, and thine oil."[2]

By irrigation, the soil of Egypt had been rendered so fertile that Pliny compares it to that of the Leontines, formerly the most fertile part of Sicily. Certain it is that Egypt was very prolific in corn even in the days of Abraham, who had recourse to it in years of famine, and that was at least eighteen centuries before the Christian era.

Too little is known of the agriculture of the ancient kingdoms of Assyria, Babylon, Carthage, Phœnicia, and Greece, to enable any one to ascertain how they practised irrigation; but as they all had Egypt as an example in agriculture and the arts, it is probable that they had followed those practices in husbandry which were most suitable to their respective countries. The little that Xenophon says in his *Anabasis* of the husbandry of Persia, would lead to the belief that canals had been cut from rivers to irrigate the country after the manner of Egypt.

The sagacious Romans, it is well known from the writings of their rustic countrymen, adopted irrigation on an extensive scale, as one of the best means of improving land. The

[1] Gen. xiii. 10.

[2] Deut. xi. 10, 11, 13, 14.

oldest Roman rustic writer, Cato, expressed his opinion that the way to become rich quickly was "by grazing cattle well," and hence he gives the preference to meadows. He does not maintain that grass is the most valuable crop which the land can produce, for he only places meadows in the fifth degree of value, giving preference in this respect to vineyards, watered gardens, willow fields, and olive gardens, but that they yielded most profit in proportion to the expense attending them, and they were always ready; hence their ancient name, *parata*. Agreeably to this opinion, Cato recommends the formation of meadows, and particularly of water-meadows, whenever there is a command of water: *Prata irrigua, si aquam habebis, potissimum facito.*[1] Columella recommends the same precept, and enters more minutely into the kinds of soils which should be converted into water-meadows, and of the nature of the surface best adapted to them, as well as the management of the water in the time of irrigation. "Land that is naturally rich," says he, "and that is in good heart, does not need to have water set over it; and it is better hay which nature of its own accord produces in a juicy soil, than what water draws from a soil that is overflowed. This, however, is a necessary practice when the poverty of the soil requires it; and a meadow may be formed either upon stiff or free soil, though poor, when water may be set over it. Neither a low field with hollows, nor a field broken with steep rising ground, are proper; the first, because it contains too long the water collected in the hollows; the last, because it makes the water run too quickly over it. A field, however, that has a moderate descent may be made a meadow, whether it is rich or so situated as to be watered; but the best situation is where the surface is smooth, and the descent so gentle as to prevent either showers or the rivers that overflow it from remaining long; and on the other hand, to allow the water that comes over it quietly to glide off. Therefore, if in any part of a field intended for a meadow, a pool of water should stand, it must be let off by drains, for the loss is equal, either from too much water or too little grass."[2] But none of the Roman rustic writers give directions *how* a *water*-meadow should be made, nor say any thing about the utility of sluices, although Columella gives minute directions about the formation of *dry* meadows. It does not appear, moreover, that they were acquainted with the raising of turf and laying it down again for meadows, because they only recommend hay-seeds from the hay-lofts and cribs to be sown, and deprecate the watering and pasturing of cattle on the new meadows till the surface becomes hard. There is no specific notice taken by any of them of how long a period meadows should be watered, if one sentence of Pliny be excepted, wherein he directs that "meadows ought to be watered immediately after the equinox, and the waters restrained whenever the grass shoots up into the stalk;"[3] but there is no hint whether they should be laid dry at intervals.

Pliny alone mentions watering before the first crop of hay is cut, on the principle that wet grass, whether wetted by water or dew, is cut more easily than dry: *Noctibus roscidis secari melius.*[4] The Romans were in the custom of cutting their meadows at least twice a-year, in May and August or September, and making hay of both these cuttings; but meadows for forage were cut sometimes four times. The autumnal hay was emphatically called *cordum*, and being soft, and sweeter than hay come to its full growth, it was the kind most proper to be given to sheep in winter. The produce of the Roman meadows appears to have been very considerable, and it is therefore no wonder that they put such a high value on grass-land. Both Columella and Pliny estimate it a day's work for a man to mow a *jugerum* and bind 1200 bundles of hay, of four pounds each. According to a calculation made by Dr Dickson, these quantities would give a produce of 265 hay stones, of 22 lb. to the stone, per acre (416 imperial stones per imperial acre), of prepared hay, besides the autumnal crop and the rakings taken up afterwards, and which may be estimated at one-half more.[5] This is not the proper place to describe the Roman method of making hay, which differed from the method of this country, but having alluded to hay having been bound in bundles, it may not be irrelevant to state that the Romans made up their hay into bundles of four pounds each before they carried it into the barns or haylofts, and that they never ricked it but in rainy weather.

Immediately after the fall of the Roman empire, agriculture declined, and was kept in a very depressed state during the middle ages, which depression, with respect to agriculture, lasted about ten centuries. It need therefore excite no surprise that the general agriculture of Italy was not much improved, from what it had been amongst the Romans, till after the revival of letters. Irrigation was perhaps the only branch of agriculture which received improvement or extension before the expiration of the dark ages; and its improvement at that time was even confined to the north of Italy. The irrigation of Lombardy to this day forms the principal feature of its agriculture. The Lombard kings, following the example of the Romans, encouraged and extended irrigation, and they were ably assisted by the inmates of their numerous and wealthy religious establishments.

Under these favourable auspices, irrigation had been extended on a great scale in Lombardy as early as 1037; and such expert hydraulic engineers had the monks of Chiarevalle become, that they were consulted and employed as such by the Emperor Frederick I. in the thirteenth century; and, ever since, so assiduous has been the care with which the agriculturists in Lombardy have preserved entire, and in good working order, their water-meadows, that at the present day no other part of the globe can exhibit that operation on so grand a scale and in such excellent order, and producing so rich a pasturage, verdant throughout the year. The largest rivers in the north of Italy, the Po, the Adige, the Tagliamento, and others, are put under requisition for a supply of water in summer and winter, for the purposes of irrigation; the whole country from Venice to Turin being almost one continued water-meadow. But there irrigation is not confined to grass-land; water being also conducted between the ridges of corn-land; in the hollows between drilled crops; among vines; and over the flats appropriated to the production of rice: and it is also used to deposite mud, in the manner of warping, where it contains sediment. Irrigation naturally passed from Lombardy into the south of France, where it is used to raise many of the more valuable productions of the soil. Spain to this day employs irrigation to so considerable an extent, that few crops are there raised without it. Some water-meadows in the neighbourhood of Salisbury, in Wiltshire, which are said to have existed from time immemorial, have led to the belief that irrigation has been practised in Britain from the time of the Romans. It is, indeed, extremely probable, that had the Romans constructed such works during their sojourn in Britain, the pastoral habits of their Saxon successors would have preserved them from destruction. But be this as it may, it is certain that irrigation after the method of Italy was not extensively introduced into Britain till the sixteenth century, when it was attempted on a large scale in Cambridgeshire, on the estate of Barbraham, by one Pallavicino, the collector of Peter's pence in the reign of Queen Mary, but who, on the accession of Elizabeth, had the art to turn Protestant, and

[1] Cat. cap. ix. [2] Col. lib. 2. cap. xvii. [3] *Nat. Hist.* lib. 18, cap. xxvii. [4] *Ib.* lib. 18, cap. xxviii.
[5] *Husbandry of the Ancients*, vol. ii. p. 321.

purchase that estate with the balance of money which he had in his possession, amounting it is said to L. 30,000 or L. 40,000, and appropriate it to his own use.[1] This dishonest experiment of Pallavicino was so gross, that his example as an irrigator was not followed at the time, nor indeed were many water-meadows formed in England till the end of the last or beginning of the present century. Since that time, many of them have been scientifically made both in England and in Scotland, which all have proved how profitably irrigation might be extended, and of which a few successful examples have been enumerated. As might be expected from the nature of the climates, irrigation is extensively practised in India, China, and parts of America, particularly Mexico; but as the irrigation of those countries presents no features peculiarly different from that related of Egypt and Italy, it is unnecessary to enlarge upon it.

VII. THEORY OF IRRIGATION.

The theory of irrigation, as propounded by the late Sir Humphrey Davy, is given by him in these words: "Water is absolutely essential to vegetation; and when land has been covered with water in the winter or in the beginning of spring, the moisture which has penetrated deep into the soil, and even the subsoil, becomes a sort of nourishment to the roots of the plants in the summer, and prevents those bad effects which often happen in lands in their natural state from a long continuance of dry weather. When the water used in irrigation has flowed over a calcareous country, it is generally found impregnated with carbonate of lime, and in this state it tends, in many instances, to ameliorate the soil. Common river water also generally contains a certain portion of organizable matter, which is much greater after rains than at other times, and which exists in the largest quantity when the stream rises in a cultivated country. Even in cases where the water used for flooding is pure, and free from animal and vegetable substances, it acts by causing the more equable diffusion of nutritive matter existing in the land; and in very cold seasons it preserves the tender roots and leaves of the grass from being affected by frost. . . . In general, those waters which breed the best fish are the best fitted for watering meadows; but most of the benefits of irrigation may be derived from any kind of water. It is, however, a general principle, that waters containing ferruginous impregnations, though possessed of fertilizing effects, when applied to a calcareous soil, are injurious on soils that do not effervesce with acids; and that calcareous waters, which are known by the earthy deposite they afford when boiled, are of most use on siliceous soils, or other soils containing no remarkable quantity of carbonate of lime."[2] To show the protective power of water against cold, it is only necessary to state the well-known physical fact, that water is of greater specific gravity at 42° Fahrenheit than at the freezing point of 32°; and hence water in contact with the roots of grass is rarely below 40°, a degree of temperature not at all prejudicial to the living organs of plants. Professor Rennie, of King's College, London, has recently given another theory of irrigation. It was promulged by M. De Candolle of Geneva, in his *Physiologie Vegetale*, and his views have recently been corroborated by the experiments of M.r Macaire of Geneva, that plants exude an excretion from their roots into the soil, and that this excretion is detrimental to the healthy growth of the same kind of plants which produced it. Hence it is concluded that grasses do not continue permanently in a healthy state in the same site, because they are in time injuriously affected by their own excretions, which, encouraging the growth of plants of a different nature, such as mosses, they spring up and extirpate the grasses. It is supposed to be probable that every species of grass is not alike affected by its own, or the excrementitious matter from other grasses, and therefore some species withstand the poison longer than others. Now, the water of irrigation, in its descent through the soil and subsoil, washes away or carries off in solution the injurious excrementitious matter exuded by the grasses, and thereby cleanses the soil in which they are growing free of it. Hence the *perennial verdure* of *irrigated* grass.[3] These theories establish four advantages which are derivable from irrigation. It supplies moisture to the soil, necessary in dry seasons and in tropical countries; it affords protection to plants against the extremes of heat and cold; it disseminates manure most minutely to plants; and it washes away injurious matter from the roots of plants.

Whichever theory is adopted, or both of them, for they are not inconsistent with each other, the benefits derivable from irrigation are purely mechanical; they have no reference to chemical action. The opinion of Sir Humphry Davy, therefore, that "in the artificial watering of meadows, the beneficial effects depend upon many different causes, some *chemical*, some mechanical,"[4] appears very problematical. Chemical action only commences after irrigation has ceased. This conclusion will appear evident, when the following particulars have been considered.

The operation of water bringing matter into minute subdivision; the sediment which it contains when used in irrigation being minutely distributed around the stems of the plants; water protecting plants in irrigation against the extremes of heat and cold, by completely covering and embracing every stem and leaf; and the supplying of moisture to the soil, and washing excrementitious matter out of it, are all purely mechanical operations. Warping is obviously a mechanical operation. Could the hand of man distribute manure around the roots and stems of grass as minutely and incessantly as turbid water; could it place a covering of woollen manufacture upon each blade and around each stem of grass, as completely as water can embrace each plant and keep it warm; could it water the grass as quietly and constantly as the slow current of irrigation; and could it wash away injurious matter from the soil as delicately around the fibres of the roots of grass as irrigating water, there would be no need of irrigation; the husbandman could then command at will verdant pasturage for his flocks and herds throughout the year, and in the driest season. His mechanical agency would be as effective as that of irrigation. But the relative powers of things being as at present constituted, man employs irrigation as the instrument of his will, and attains the maintenance of his live-stock by inducing Nature to assist him in a work in which she undoubtedly displays her superiority over him both in industry and dexterity. (K. K. K.)

IRRITABILITY, in *Anatomy* and *Medicine*, a term first invented by Glisson, and adopted by Haller, to denote an essential property of all animal bodies, which exists independently of, and in contradistinction to, sensibility. This ingenious author calls that part of the human body *irritable*, which becomes shorter upon being touched; *very irritable*, if it contracts upon a slight touch; and the contrary, if by a violent touch it contracts but little. He calls that

[3] *Quarterly Journal of Agriculture*, vol. v. p. 24.
[4] *Agricultural Chemistry*, p. 305.

a sensible part of the human body, which, upon being touched, transmits the impression thereof to the soul; and in brutes, he calls those parts sensible, the irritation of which occasions evident signs of pain and disquiet in the animal. On the contrary, he calls that insensible, which being burned, torn, pricked, or cut till it is quite destroyed, occasions no sign of pain or convulsion, nor any sort of change in the situation of the body. From the result of many cruel experiments, Haller concludes that the epidermis is insensible; that the skin is sensible in a greater degree than any other part of the body; that the fat and cellular membrane are insensible; and that the muscular flesh is sensible, its sensibility being ascribed by him rather to the nerves than to the flesh itself. The tendons, he says, having no nerves distributed to them, are insensible. The ligaments and capsulæ of the articulations are also believed to be insensible; and hence Haller infers, that the sharp pains of the gout are not seated in the capsulæ of the joint, but in the skin, and in the nerves which creep upon its external surface. The bones are all insensible, says Haller, except the teeth; and likewise the marrow. Under his experiments, the periosteum and pericranium, the dura and pia mater, appeared insensible; and he infers, that the sensibility of the nerves is owing to the medulla, and not to the membranes. The arteries and veins are held to be susceptible of little or no sensation, excepting the carotid, the lingual, temporal, pharyngal, labial, thyroidal, and the aorta near the heart, the sensibility of which is ascribed to the nerves that accompany them. Sensibility is allowed to the internal membranes of the stomach, intestines, bladder, ureters, vagina, and womb, on account of their being of the same nature with the skin; the heart is also admitted to be sensible, but the lungs, liver, spleen, and kidneys, are possessed of a very imperfect, if any, sensation. The glands, having few nerves, are endowed with only an obtuse sensation. Some sensibility is allowed to the tunica choroides and the iris, though in a less degree than the retina; but none to the cornea. Haller concludes, in general, that the nerves alone are sensible of themselves; and that, in proportion to the number of nerves apparently distributed to particular parts. such parts possess a greater or less degree of sensibility.

Irritability, he says, is so different from sensibility, that the most irritable parts are not at all sensible, and *vice versa.* He alleges facts to prove this position, and also to demonstrate, that irritability does not depend upon the nerves, which are not irritable, but upon the original formation of the parts which are susceptible of it. Irritability, he says, is not proportioned to sensibility; and in proof of this, he observes, that the intestines, though rather less sensible than the stomach, are more irritable, and that the heart is very irritable, though it has but a small degree of sensation.

Irritability, according to Haller, is the distinguishing characteristic between the muscular and cellular fibres; and hence he determines that the ligaments, periosteum, meninges of the brain, and all the membranes composed of the cellular substance, are void of irritability. The tendons are not irritable; and though he does not absolutely deny irritability to the arteries, yet his experiments on the aorta produced no contraction. The veins and excretory ducts are in a small degree irritable, and the gall-bladder, the ductus choledochus, the ureters and urethra, are only affected by a very acrid corrosive; but the lacteal vessels are considerably irritable. The glands and mucous sinuses, the uterus in quadrupeds, the human matrix, and the genitals, are all irritable; as are also the muscles, particularly the diaphragm. The œsophagus, stomach, and intestines, are irritable; but of all the animal organs, the heart is endued with the greatest irritability. In general, there is nothing irritable in the animal body but the muscular fibres; and the vital parts are the most irritable. This power of motion, arising from irritations, is supposed to be different from all other properties of bodies, and probably resides in the glutinous mucus of the muscular fibres, altogether independently of the influence of the soul. The irritability of the muscles is said to be destroyed by drying the fibres, congealing the fat, and more especially by the use of opium in living animals. The physiological system, of which an abstract has now been given, has been adopted and confirmed by Castell and Zimmermann, and also by Brocklesby, who suggests, that irritability, as distinguished from sensibility, may depend upon a series of nerves different from such as serve either for voluntary motion or sensation. This doctrine, however, has been controverted by M. le Cat, and particularly by Dr Whytt, in his Physiological Essays.

IRROGATIO, a term of the Roman law, signifying the instrument in which were put down the punishments that the law provided against such offences as any person was accused of by a magistrate before the people. These punishments were first proclaimed *viva voce* by the accuser, and this was called *Inquisitio.* But the same being immediately afterwards expressed in writing, took the name of *Rogatio,* in respect of the people, who were to be consulted or asked about it, and was called *Irrogatio* in respect of the criminal, as it imported the mulct or punishment assigned him by the accuser.

IRROMANGO, or ERROMANGO, one of the New Hebrides islands, is about 24 or 25 leagues in circuit; the middle of it lies in Lat. 18° 54′ S.; Long. 169° 19′ E. See AUSTRALASIA.

IRTISH, a large river of Asia, in Siberia, which rises amongst the hills of the country of the Kalmucks, and, running north-east, falls into the Oby near Tobolsk. It abounds with fish, particularly sturgeon, and delicate salmon.

IRVINE, a seaport town and royal burgh of Scotland, in the bailiwick of Cunningham, and county of Ayr; it is agreeably situated at the mouth of a river of the same name on the Frith of Clyde, at the distance of eleven miles north of Ayr, sixty-seven from Edinburgh, twenty-five south-south-west of Glasgow, and six and a half west of Kilmarnock. It is a town of considerable antiquity, as appears by the records of the burgh, Alexander II. having granted a charter to the burgesses, confirming some other royal grants. It is a small but thriving place, consisting, besides smaller streets, of one broad street, running from south-east to north-west the whole length of the town, on the south side of the river, but connected with the town by a bridge. The road leading to the harbour is lined by a row of houses on either side, and mostly inhabited by seafaring people; and the road leading to Ayr is provided with houses in the same way. The bridge of Irvine is the widest and handsomest in the county. This burgh possesses a town-house, a parish church, and three other places of worship. There is an excellent academy, in which the higher branches are taught, a subscription free-school, several private schools, a news-room, and a subscription library. This port had formerly employed in the herring fishery several busses, that is, vessels fitted out under certain regulations to entitle them to a bounty. At present there are about one hundred vessels belonging to the port, tonnage 11,000, navigated by about seven hundred and thirty men. About twenty-one of these vessels are employed in the North American trade, three or four in the Mediterranean, one to India, and the remainder in the Irish or coast trade. There is a considerable timber and grain trade at this port, and a very extensive coal-trade. In 1834, the quantity of coal exported, principally to Ireland, was 91,462 chalders, equal to about 137,600 tons. The annual revenue of customs is from L.3000 to L.4000. Ship-building, chain, cable, and rope-making are carried on to some extent in Irvine. As a royal burgh it is governed by a provost, two bailies, a dean of guild, treasurer, and twelve councillors. The population of the town and parish was 7007 in 1821, and 7200 in 1831.

ISAAC, the Jewish patriarch, and an example of filial obedience, died 1716 before Christ, aged one hundred and eighty years.

ISÆUS, a celebrated Greek orator, whose birth-place was uncertain even in the time of Dionysius of Halicarnassus, who treats of him at considerable length. Some thought him a native of Athens, and others of Chalcis, in the island of Eubæa. The precise dates of his birth and death are not given, but we know that he flourished after the Peloponnesian war, about B. C. 400, and continued to take part in public affairs till the reign of Philip, B. C. 364. He was the pupil of Lysias and Isocrates, but he is chiefly distinguished as being the master of Demosthenes, who seems to have preferred him to all the orators of that age. The style of Isæus so much resembled that of Lysias, that Dionysius says it was difficult to distinguish them. It is simple, elegant, and full of vivacity, so that it has passed into a proverb, *Isæo torrentior*. (*Juv.* iii. 74.) He was chiefly employed in courts of law, and all the orations of his which have been preserved, were delivered in defence of his clients. Of sixty-four which were attributed to him, of which fourteen were considered as apocryphal in the time of Photius, there are only ten now preserved. The most esteemed edition of his works is that of *Reiske*, Leipsic, 1775, and of *Shoëmann*, Gryphiswald, 1831. They have been translated into English by W. Jones, London, 1779; into French by Auger, Paris, 1783; and into German by Shoëmann, Stuttgart, 1830. Another discourse of Isæus (*De Meneclis Hæreditate*) was discovered in a manuscript of the Library of St Lawrence, at Florence, and published by Tyrwith, London, 1785.

This Isæus ought not to be confounded with Isæus, another celebrated orator, who lived at Rome in the time of Pliny the younger, about the year 97.

ISAIAH, or *the Prophecy of Isaiah*, a canonical book of the Old Testament. Isaiah is the first of the four greater prophets; the other three being Jeremiah, Ezekiel, and Daniel. This prophet was of royal descent, his father Amos being brother to Azariah king of Judah. The first five chapters of his prophecy relate to the reign of Uzziah; the vision in the sixth chapter happened in the time of Jotham; the following chapters, to the fifteenth, include his prophecies under the reign of Ahab; and those which were made under the reigns of Hezekiah and Manasseh, are related in the subsequent chapters to the end. Isaiah foretold the deliverance of the Jews from their captivity in Babylon by Cyrus, one hundred years before it came to pass. But the most remarkable of his predictions are those concerning the Messiah, which describe not only his descent, but all the remarkable circumstances of his life and death. The style of this prophet is noble, nervous, and sublime, insomuch that Grotius calls him the Demosthenes of the Hebrews. However, the profoundness of his thoughts, the loftiness of his expressions, and the extent of his prophecy, render him one of the most difficult of all the prophets; and the commentaries which have been hitherto written on his prophecy fall short of a full explication of it. Bishop Lowth's translation, published in 1778, throws considerable light on the composition and meaning of *Isaiah*.

ISAURA, or Isaurus, in *Ancient Geography*, a strong city of Mount Taurus, in Isauria, which was twice demolished; first by Perdiccas, or at least by the inhabitants, who, through despair, destroyed themselves by fire, rather than fall into the hands of the enemy; again by Servilius, who thence took the surname *Isauricus*. Strabo says there were two Isauras, the old and the new, but so near that they were often confounded.

ISAURIA, a rugged and mountainous country, touching Pamphylia and Cilicia on the north, situated almost in Mount Taurus, and taking its name from Isaura; and, according to some, extending by a narrow slip to the Mediterranean. Stephanus, Ptolemy, and Zosimus, make no mention of places on the sea; though Pliny and Strabo do; but the latter are doubtful whether these are places in Isauria Proper, or in Pamphylia, or in Cilicia.

ISCA Dumniorum, in *Ancient Geography*, a town in Britain; now Exeter, capital of Devonshire. Lat. 5° 44′, Long. 3° 40′ W.

Isca *Silurum*, in *Ancient Geography*, the station of the *Legio Augusta Secunda* in Britain; now *Caerleon*, a town of Monmouthshire, on the Uske.

ISCHALIS, or Iscalis, in *Ancient Geography*, a town of the Belgæ in Britain; now *Ilchester*, in Somersetshire, on the river Ill.

ISCHIA, an island in the Mediterranean Sea, on the north-west side of the Bay of Naples, of volcanic origin, but fertile in wheat, wine, and fruits. It contains about twenty-seven square miles. The mountain Spomea, in height 2500 feet, is an extinguished volcano, but has woods and good pasture land, and several dairies are maintained, in which excellent cheese is made. It contains the capital, of the same name as the island, with 3140 inhabitants. The whole of the population amounts to 22,470 persons, who are active in producing silk, wine, excellent oil, and various kinds of fruit.

ISCHURIA, ισχουρια (formed from ἰσχω, *I stop*, and ὀυρον, *urine*), in *Physic*, a disease consisting in an entire suppression of urine.

ISELASTICS, a kind of games, or combats, celebrated in Greece and Asia, in the time of the Roman emperors. The victors at these games had very considerable privileges conferred on them. They were crowned on the spot immediately after their victory, had pensions allowed them, were furnished with provisions at the public cost, and were carried in triumph to their own country.

ISELWORTH, a town of the county of Middlesex, in the Hundred of the same name, eight miles from London. It is pleasantly situated on the banks of the Thames, and contains Sion House, belonging to the Duke of Northumberland, and several other mansions of high respectability. The principal industry is exercised in gardening, for the supply of the metropolis. The inhabitants amounted in 1801 to 4346, in 1811 to 4661, in 1821 to 5269, and in 1831 to 5590.

ISENBERG, now a province of the principality of Hesse Cassel, having been added to it when the former sovereign, who is still the chief proprietor, was mediatised. It is about 100 square miles in extent, is a hilly district, with extensive woods, is watered by the rivers Kinzig and Bracht, and the population living in four market-towns and forty-four villages, to the amount of 47,500, subsist chiefly by agricultural occupations. None of the four towns in it, except Berstein, has a thousand inhabitants.

ISERE, a department of the south of France, formed out of the ancient divisions of Graisivaudan and Bienois, which were formerly portions of Dauphiné. It extends over 3564 square miles, or, according to the royal almanack, 841,230 hectares. It is divided into four arrondissements, and these into 45 cantons, with 558 communes, having 471,660 inhabitants. The latter mostly adhere to the Catholic Church, but there are about 7000 Protestants. The common language is a patois, composed of Celtic, Latin, French, Italian, and Greek, but in which the Latin words predominate. The pure French, with the southern accent, is generally spoken in the towns. The face of the country is generally hilly, and in many parts mountainous, exhibiting most picturesque natural scenery, rising gradually from the plain through which the Rhone flows to the lofty elevations bordering on Savoy, where the highest of them, the Col de Saix, is 10,296 feet above the level of the sea. Some of the numerous valleys which extend between the ranges of mountains are of peculiar beauty, especially the valley of the Isère or Graisivaudan, which is nearly fifty miles in length, and considered as the most delightful district of France. It resembles a well cultivated garden, through which, with many windings, the river flows, between meadows and corn-fields, where scattered mulberry and other fruit trees, fine vineyards, and small woods on the sides of the hills, are ornamented by country houses and neat villages intermingled amongst them. Though, from the elevation, a great portion of the department remains uncultivated, and is incapable of cultivation, yet the other portions are fertile and highly productive. The soil is sandy, mixed with small shells in the valleys, resting on granite, and is easily worked; it is well irrigated, and adapted to almost every vegetable production. The only navigable rivers are the Rhone and the Isère, whose contributary streams are numerous. There are also some canals, which serve the double purpose of navigation and of irrigation. There are several mountain lakes within the department, and some of them are 7548 feet in height. The climate varies with the elevation; some of the eastern sides of the mountains are constantly covered with snow, whilst the valleys are in summer intensely hot. The chief agricultural products are wheat, maize, barley, potatoes, hemp, flax, rapeseed, stone fruits, wine, chestnuts, filberts, and some medicinal plants, besides cattle and game. There are mines which yield small portions of silver, copper, iron, lead, and coal, but none of them is extensively worked. The manufactures are cotton, silk, and woollen goods, earthenware, gloves at the capital, Grenoble, in large quantities, fine linen, paper, glass, liqueurs and brandy. There is also much leather prepared for the glover's trade.

ISERLON, a city of Prussia, the capital of a circle of the same name in the Arensberg division of the province of Westphalia. It stands on the river Baaren, and is one of the first manufacturing places in the kingdom for silks, velvets, and ribbons, and also has manufactories of cutlery, and other iron goods, with extensive linen weaving and bleaching. It contains two Lutheran, one Reformed, and one Catholic church, 786 houses, and 5690 inhabitants. Lat. 51° 25′ 6″, and Long. 7° 35′ 22″ E.

ISH, in *Scotch Law*, signifies *expiration*. Thus we say "the *ish* of a lease." It signifies also *to go out*; thus we say "free *ish* and entry" from and to any place.

ISIA, Ισεια, feasts and sacrifices anciently solemnized in honour of the goddess Isis. The Isia were full of the most abominable impurities, for which reason, those who were initiated into them were obliged to take an oath of secrecy. They were held for nine days successively, but grew so scandalous, that the senate abolished them at Rome, under the consulate of Piso and Gabinius. They were re-established by Augustus, and the Emperor Commodus himself assisted at them, appearing amongst the priests of that goddess with his head shaven, and carrying the Anubis.

ISIAC TABLE, is one of the most considerable monuments of antiquity discovered at Rome in 1525, and supposed, by the various figures in bas-relief upon it, to represent the feats of Isis, and other Egyptian deities. There have been various opinions as to the antiquity of this monument. Some have supposed that it was engraved long before the time when the Egyptians worshipped the figures of men and women; but others, amongst whom is Bishop Warburton, apprehend that it was made at Rome by persons attached to the worship of Isis. Dr Warburton considers it as one of the most modern of the Egyptian monuments, on account of the great mixture of hieroglyphic characters which it bears.

ISIACI, priests of the goddess Isis. Dioscorides tells us, that they bore a branch of sea wormwood in their hands instead of olive. They sung the praises of the goddess twice a-day, namely, at the rising of the sun, when they opened her temple, after which they begged alms the rest of the day, and returning at night, they repeated their orisons, and shut up the temple. The Isiaci never covered their feet with any thing but the thin bark of the plant papyrus, which occasioned Prudentius and others to say that they went barefooted. They wore no garments except linen, because Isis was the first who taught mankind the mode of preparing this commodity.

ISIDORUS, called DAMIATENSIS, or PELUSIOTA, from his having lived in a solitude near that city, was one of the most famous of all St Chrysostom's disciples, and flourished in the time of the general council held in 421. We have upwards of two thousand of his epistles in five books. They are short, but well written, in Greek. The best edition is that of Paris, in Greek and Latin, printed in 1638, in folio.

ISIS, a celebrated deity of the Egyptians. Some suppose her to be the same as Io, who was changed into a cow, and restored to her human form in Egypt, where she taught agriculture, and governed the people with mildness and equity, for which reasons she received divine honours after death. According to some tarditions mentioned by Plutarch, Isis married her brother Osiris, and was pregnant by him even before she had left her mother's womb. These two ancient deities, as some authors observe, comprehended all nature and all the gods of the heathens. Isis was the Venus of Cyprus, the Minerva of Athens, the Cybele of the Phrygians, the Ceres of Eleusis, the Proserpine of Sicily, the Diana of Crete, and the Bellona of the Romans. Osiris and Isis reigned conjointly in Egypt; but the rebellion of Typhon, the brother of Osiris, proved fatal to this sovereign. The ox and the cow were the symbols of Osiris and Isis; because these deities, whilst on earth, had diligently applied themselves to the cultivating of the earth. Since Isis was supposed to be the moon, as Osiris was the sun, she was represented as holding a globe in her hand, with a vessel full of ears of corn. The Egyptians believed that the yearly and regular inundations of the Nile proceeded from the abundant tears which Isis shed for the loss of Osiris, whom Typhon had basely murdered. The word *Isis*, according to some, signifies "ancient," and on that account the inscriptions on the statues of the goddess were often in these words: "I am all that has been, that shall be; and none amongst mortals has hitherto taken off my veil." The worship of Isis was universal in Egypt, and her priests were obliged to observe perpetual chastity; their heads were closely shaved, and they always walked barefooted, and clothed themselves in linen garments. They never ate onions, they abstained from salt with their meat, and they were forbidden to eat the flesh of sheep and of hogs. During the night they were employed in continual devotion near the statue of the goddess. Cleopatra, the beautiful queen of Egypt, was wont to dress herself like this goddess, and affected to be called a second Isis.

ISIS, or *Thames*, a river that takes its rise in Gloucestershire, and flows through only a small part of Wiltshire. It enters this county near its source, and begins to be navigable for boats at Cricklade; but after running in a serpentine manner about four miles, it leaves Gloucestershire at a village called Castle Eaton.

ISJUM, a city of the province Ukraine in Russia, the capital of a circle of the same name on the river Jszumez, which near to it falls into the Donez. It is surrounded with walls, but in a neglected condition; and contains four churches, 718 houses, and 4500 inhabitants, whose chief trade consists in the sale of corn and cattle. Lat. 49° 12′ 30″ N.; Long. 37° 30′ 5″ E.

ISLA DE LA GENTE HERMOGA, or Island of Handsome

People, an island in the Pacific Ocean, discovered by Mendana, about six leagues in circumference. Lat. 10° S.; Long. 175° 10′ W.

ISLA DE LEON, a city of Spain, in the kingdom of Seville, and in the province of Andalusia. It is a place generally containing 40,000 inhabitants, but from being within the line of defence of the Spanish troops and the garrison of Cadiz, during the siege it was supposed to contain more than double that number. When the French armies were in possession of the rest of Spain, this city became the refuge of the loyal party, the place of assembly for the national representatives, and the seat of the government. From being near the arsenal of Caraccas, the officers and workmen employed there, found it convenient to take up their residence in this city. The streets are wide, the houses large, the public buildings splendid, and its whole appearance gives it an air of great magnificence. It is separated from the continent by the narrow but navigable river Sante Petri, over which is an ancient bridge called Puente de Zuarzo, generally, but erroneously, believed to have been built by Julius Cæsar; it is, however, known to have been erected by Cornelius Balbo the younger, seventeen years before the Christian era. The foundations are now the same as then existed, but the upper works, and some of the arches, were built in 1437. On both sides, but especially towards the continent, the river has extensive and boggy marshes, which can only be crossed by means of a narrow causeway, exposed to the attacks of several heavy batteries. The strength of this place, and the secure retreat from it to Cadiz, of still greater strength in case of emergency, made it the natural and valuable asylum of all that remained of freedom in Spain from the year 1810, till the result of the battle of Salamanca compelled the French to evacuate Andalusia. The marshes on the banks of the Sante Petri afford prodigious quantities of salt, crystallized by the heat of the sun. It is piled in heaps of a pyramidical form; and when the rain dissolves the upper part, the sun crystallizes it again, and thus forms a roof of a solid cake of salt, and defends the heap from the future effects of any bad weather. It is permitted to be exported on payment of a very trifling duty, and numerous ships are loaded with it. What is conveyed to the interior becomes the subject of a royal monopoly, and is subject to a very heavy tax. Lat. 38° 53′ 16″ N.; Long. 5° 40′ 31″ W.

ISLAM, or ISLAMISM; the true faith, according to the Mahommedans. See MAHOMMEDANISM.

ISLAMABAD, a town of Bengal, in the district of Chittagong, of which it is the capital. It is situated on the western bank of the Chittagon, near about ten miles from its junction with the sea. It carries on a considerable trade, and ships are also built there, and sent to Calcutta for sale. This town was early known to the Portuguese, by whom it was called Porto Grando. It was taken from the rajah of Arracan by the Moguls in 1666; and was at that period well fortified with 1200 cannon. Its name was changed from Chittagong to Islamabad. In 1689, the English made an unsuccessful assault upon it. Since it was ceded to the British in 1760, the fortifications have been allowed to go into decay. The entrance to the river is dangerous without a pilot, as it has only four fathoms over the bar, and afterwards deepens to from five to seven fathoms. The entrance to the river is in 22° 13′ N. The town stands in long. 91° 42′ E.; lat. 22° 22′ N. This is also the name of a considerable town of Cashmeer, situated on the north side of the river Ihytyur, over which is a wooden bridge eighty yards in length. Its houses are built of stone, with gardens on their roofs; and its principal manufacture is shawls. Lat. 34° 6′ N.; Long. 74° 7′ E.

ISLAMNAGUR, a town of Hindostan, in the Mahratta territories, province of Malwah, five miles north-east from Bossal, in lat. 23° 19′ N.; long. 77° 31′ E. There are many small places of this name in Hindostan.

ISLAMPOOR. There are two towns of this name in Hindostan, one in the province of Ajmeer, seventy-seven miles north from Zeypoor. Lat 27° 4′ N.; long. 75° 23′ E. Another in the province of Bahar, district of Bahar, thirty-five miles south from Portna. Lat. 25° 7′ N.; long. 85° 15′ E.

ISLAND, a tract of dry land encompassed with water; in which sense it stands contradistinguished from CONTINENT, or TERRA FIRMA.

ISLE, a city of the arrondissement of Gaillac, in the department of the Tarn in France. It stands on the river Tarn, and is an ill-built manufacturing town, containing 6520 inhabitants, who make various kinds of woollen goods, and trade largely in wine.

ISLEBIANS, in ecclesiastical history, a name given to those who adopted the sentiments of a Lutheran divine of Saxony, called John Agricola, a disciple of Luther, and a native of Isleb, who, interpreting literally some of the precepts of St Paul regarding the Jewish law, declaimed against the necessity of good works. See ANTINOMIANS.

ISLINGTON, a large parish in the hundred of Ossulton, in the county of Middlesex, one mile and a half from London. It rises in a gentle declivity from the metropolis, but, by the houses connecting with it, appears to be only a prolongation of the city. It is chiefly occupied by persons carrying on trade in London, or by those who have retired from commerce. It contains no very splendid mansions, but a great number of respectable and comfortable dwellings. It contains the hamlets of Upper and Lower Holloway, and part of Newington Green and Kingsland. Being on the great north road, carriages are passing through it at all hours. Besides the parish church it has three others, and chapels for sectaries of every description. The New River passes through the parish, and the Regent's Canal. The latter, by a tunnel, goes under the principal street, and under the New River, and thus conveys coals and other heavy articles from the Thames at a cheap rate. The New River head, from which a great part of the metropolis is supplied with water, is in this parish, as well as the minor theatre known as Sadler's Wells. A mineral water here was once frequented for its medicinal qualities, but the fashion seems to be changed, as it is now rarely resorted to. A collegiate institution has been lately founded at Highbury in this parish, for the education of dissenting ministers of the class of Independents. The population of the parish amounted in 1801 to 10,212, in 1811 to 15,065, in 1821 to 22,417, and in 1831 to 37,316.

ISMAELITES, the descendants of Ismael, dwelling from Havila to the wilderness of Sur, towards Egypt, and thus overspreading Arabia Petræa; wherefore Josephus calls Ismael the founder of the Arabs.

ISMAIL, a town of the Russian province Bessarabia, the capital of a circle of the same name. It is situated on an arm of the Danube, is strongly fortified, and has become celebrated for the carnage which attended its capture in 1789 by Suwarrow. Since that period it has not recovered its former importance, and contains but few inhabitants, with little commerce or produce. Lat. 45° 21′ 30″; Long. 28° 44′ 35″ E.

ISMARUS, in *Ancient Geography*, a town of the Cicones in Thrace, giving name to a lake, and by Virgil called Ismara.

ISMID, a town of Asia Minor, the ancient Nicomedia, capital of Bithynia. It retains no traces of its former grandeur, nor any antiquity, except the remains of a church. It contains 750 families, and is situated on the side of a hill overlooking the Gulf of Nicomedia. Lat. 40° 39′ N.; Long. 29° 34′ E.

ISMIK, a town of Asia Minor, the ancient Nice, which now contains scarcely 300 houses, yet exhibits numerous monuments of ancient grandeur. It is situated on a lake communicating with the Sea of Marmora, and carries on some trade in silk. This place is famous in ecclesiastical history, as the seat of two councils, in 325 and 387. During the period of the crusades, it became the capital of a kingdom erected along the coast of Asia Minor. The old walls of the town may be still traced over a circumference of four miles. Lat. 40° 16′ N.; Long. 29° 50′ E.

ISOCHRONAL, is applied to such vibrations of a pendulum as are performed in the same space of time; as are all the vibrations of the same pendulum, whether the arches it describes be longer or shorter.

ISOCHRONAL *Line*, that in which a heavy body is supposed to descend without any acceleration.

ISOCRATES, one of the most celebrated rhetoricians of Athens, was born, B. C. 436, five years before the beginning of the Peloponnesian war, twenty-two years after the birth of Lysias, and fifty-four after that of Demosthenes. He died B. C. 338. He was son of Theodorus, who was a manufacturer of musical instruments, but, though of humble parentage, he seems to have enjoyed the best education which Athens could furnish. His early years were spent under Gorgias of Leontium, one of the most celebrated sophists of the age; Prodicus of Ceos, whose beautiful apologue of Hercules between Virtue and Vice, has immortalized his name; and Theramenes, who was afterwards condemned to death by the thirty tyrants, because, though their colleague, he refused to participate in their tyranny. With their assistance, Isocrates soon began to display the talents of which he was possessed, and became anxious to illustrate his name as a statesman and legislator. Nature, however, it would appear, had placed an impassable barrier against his entrance on public life, by furnishing him with a weak voice and timidity of nature which he found himself unable to overcome. Thus prevented from pursuing the path to which his inclination pointed, he determined to make his talents subservient to his fortune. He opened a school for oratory, and soon found himself surrounded by a numerous body of young men anxious to profit by his instructions. Amongst the more celebrated we may mention Theopompus, Ephorus, Isæus, Timotheus, Philiscus, and Xenophon. So numerous were the disciples of Isocrates, that Hermippus composed a work in several books respecting them. The sophists of his time were accustomed to discuss subtile points of logical casuistry; Isocrates first distinguished himself by discussing the great political interests of the time, and examining important questions of morality. As his speeches were not intended to be delivered, but to be perused in the retirement of the closet, Isocrates was obliged to pay particular attention to beauty of style, to the rounding of his periods, and avoiding whatever might prove offensive to the ear. He is said to have been employed ten years in polishing one of the most celebrated of his productions, entitled the *Panegyric*. It might be expected that this mode of proceeding would be attended with some defects; it occasioned a want of animation, a constant monotony, and often an enfeebling of the ideas, which were enveloped in a multitude of words, useful only to round the period and to produce the necessary rhythm and cadence. He was not always able to secure himself against the envy of his countrymen, and they even accused him of holding a suspicious intercourse with Philip of Macedon, with whom he kept up a constant correspondence; but he proved, by the closing scene of his life, that his intentions had always been pure, and that he had sincerely loved his country. After the battle of Chæronea, B. C. 338, so fatal to the liberties of Greece, he determined no longer to drag on a life which would be embittered by seeing his country subject to the Macedonians. He preferred to starve himself to death. Of his works we still possess twenty-one orations and nine letters. The first is addressed to Demoricus, of whom we know nothing, and is a collection of remarks and maxims for the direction of a young man's conduct. It is attributed by some critics to Isocrates of Apollonia, who is mentioned by Suidas and Harpocration. One of the finest of his productions is the *Panegyric* (Πανηγυρικος), which was written B. C. 380, with the view of putting an end to the internal dissensions of the Greeks, and inducing them to unite against the Persians. We may also mention the oration entitled Παναθηναικος, as one of the best specimens of his peculiar style, though it was composed, B. C. 342, at the advanced age of ninety-four. It is a high panegyric on the Athenians and their ancestors. Numerous editions of his works have been published. The *editio princeps* was printed at Milan in 1493, by Demetrius Chalcondylas, but the best is that by Coray, Paris, 1807. The Panegyric has been published separately by Morus, 1803, by Pinzger, Lips. 1825, and by Dindorf, Lips. 1826. Many of his other works have also been published separately.

ISOPERIMETRICAL FIGURES, in *Geometry*, are such as have equal perimeters or circumferences.

ISOSCELES TRIANGLE, in *Geometry*, one that has two equal sides.

ISPAHAN, from time immemorial the capital of the Persian monarchy, and long celebrated as one of the most splendid cities of the East, though now nearly in a state of ruin and decay. Its original name is said to have been Sipahan, which it received from the Persian kings, in consequence of its having been the general place of rendezvous for their armies. The origin of this city is lost in a remote antiquity; but it is generally supposed to have arisen from the ruins of Hecatompylos, the capital of Parthia; whilst some will have it to stand on the site of the Aspa or Aspadura of Ptolemy. It is well adapted, from its central situation with the noble river Zeinderood flowing through it, for the capital of the empire. It was under the caliphs of Bagdad that it rose to be the capital of Irak, and under their powerful protection it soon increased in wealth, population, and trade. The invasion of Timor gave a fatal blow to its rising prosperity. Ispahan was taken by his conquering army in the year 1387; and at first he contented himself with exacting a large contribution from its inhabitants But being apprised that the inhabitants meditated a nocturnal insurrection against his troops, he gave up the place to military execution; and in the indiscriminate massacre which followed, it is computed that 70,000 inhabitants perished; indeed their heads piled up in heaps on the walls of Ispahan, attested the merciless severity of the conqueror. From this desolation, owing to its favoured situation, it quickly revived; and under the early sophis great efforts were made to restore its former prosperity. But it was reserved for the renowned Shah Abbas to raise it to the height of royal magnificence, and to render it not only a luxurious capital, but the great emporium of the Asiatic world. During his reign it contained nearly a million of people, and to supply its markets required the labour of 1400 villages, whose inhabitants drew their subsistence from its prosperity. "Its bazaars," says Sir R. K. Porter, "were filled with merchandize from every quarter of the globe, mingled with the rich bales of its own celebrated manufactures."[1] It was the scene of industry, diligence, and activity; whilst the court of the great king was the resort of ambassadors from the proudest kingdoms of the East, as well as from Europe; and travellers visited it, to behold its splendours, and to enjoy the gracious reception bestowed by its monarch on the learned and ingenious of all nations. It was visited by Chardin at the beginning of the eighteenth century, and its mag-

[1] See *Travels in Georgia, Persia, &c.*, vol. i. p. 407, *et seq.*

Ispahan. nificence was such, that no city of the East could compare with it, except the capitals of Hindostan and China. Such was the state of Ispahan during the reign of Abbas the First, and also during the subsequent reign of the second Abbas. In 1722, it was taken by the Afghans, when all its prosperity and splendour were for ever extinguished by those merciless invaders. The people were massacred without mercy; the most superb edifices erected by the Persian kings were reduced to ruins; and the wall which formerly surrounded the city was entirely destroyed by them. In 1727 it was retaken by Nadir Shah, who took no pains, however, to restore its prosperity. Since this period, Ispahan has never again been a royal residence, the late sovereigns of Persia having preferred a more northern capital, particularly Teheran; and Ispahan, instead of being repaired and beautified as formerly, has gone more and more into decay, and now presents little else than a scene of ruin. Its people are in fact reduced to scarcely one-tenth of their former numbers; the streets are everywhere in ruin; the bazaars remain silent and unattended; the caravansaries are equally forsaken; its villages lie waste; and its palaces are solitary, the sounds of revelry, which were wont to be heard in the festive halls, being now succeeded by the howling of jackals and famishing dogs.

According to the ancient account of this city by Chardin, it was twenty-four miles in circuit, contained 172 mosques, 43 colleges, 1800 caravansaries, and 273 public baths. The most splendid edifice which adorned the city was the palace of Shah Abbas. It is said to have been five miles in circuit, and was divided into gardens and pleasure grounds, with summer-houses and other elegant structures. The extent and elegance of the buildings, the number and beauty of the fountains dispersed through the gardens, and the grandeur of the royal halls in the interior, are said to have surpassed any thing of the kind to be found in Europe. The walls and buildings of the palace remain still nearly entire; but it has been stripped of all its costly furniture, and every thing valuable that could be removed.

The Meydun is a large square, nearly one-third of a mile in length, and about one-half in breadth. It was formerly surrounded by a canal, bordered by very fine plane trees; but all vestiges of both are now obliterated. Its original purpose, by Shah Abbas, was for the display of horsemanship and military exercises, but it is now entirely devoted to trade, being the place of the city where the finest shops are to be found, with a second storey, in which mechanics have their working apartments; and in the middle is a market for horses and cattle. In the centre of this immense area stand some edifices remarkable for grandeur or for character. In the north-west we find the great gate or rather tower of entrance to the bazaar, on which in former times stood the celebrated clock of Ispahan. The south-eastern side of the quadrangle shews the Mesched Shah, a superb mosque, which Shah Abbas built and dedicated to Mehedi, one of the twelve imams. On the north-east is the mosque of Looft Ullah; and on the south-west the Ali-kapi, or gate of Ali, forms a majestic parallel to the bazaar porch on the opposite side. This is the most perfect piece of fine brick-work to be found in the Persian empire. Another remarkable object is the Chahar Bagh, or four gardens. The royal domain which bears that title, is a very extensive tract, inclosed with four majestic walls, and divided into gardens with pleasure-grounds. The prevailing plan of all these is that of long parallel walks, shaded by even rows of tall and umbrageous planes; and interspersed with a variety of fruit-trees, and of every kind of flowering shrub. Canals, which receive the waters of the Zeinderood, flow down the avenues in the same undeviating lines, and generally terminate in some large marble basin of a square or octagon shape, ornamented with sparkling fountains; the effect of the whole, though formal, being extremely grand. Many magnificent rivers and palaces opened into these grounds, which are now all destroyed. That at the east called Hooser Jereeb, one of the noblest edifices of Ispahan, was reduced into a heap of rubbish by the Afghans. Its garden, however, still remains, and is nearly a mile in extent. The object of this garden was to form a repository of the finest fruits which Persia produced, and which are still to be found there in the greatest perfection. The palace of Forty Pillars, which was the favourite residence of the Sefi kings, is said to exceed all our European ideas of splendour, and to realize the wonderful tales of the Arabian Nights' Entertainments. At a considerable distance from the Chehel Setoon, or the palace of the Forty Pillars, to the left of the gardens, stands the Winter Palace, containing the harem, royal arsenal, and stables, where Ashneff, the second tyrant of the Afghan invaders, held his short and cruel sway, which he stained with the blood of its native prince, the captive Shah Houssain. Close to the winter palace stands a superb structure, lately erected by the Nizam-a-Doulah, for the reception of his present majesty, should he ever visit the capital. The general style of the architecture is the same with that of the neighbouring palaces, but executed in a more light, simple, and elegant taste.

There are several very handsome bridges in Ispahan across the Zeinderood. They were all the work of Shah Abbas, built of brick, and on the same plan, being perfectly level, presenting the appearance of Roman aqueducts. Each bridge is formed of a long succession of small arches, over which the causeway is laid; and on that run two lines of arcades on each side of the bridge, affording a road for foot passengers, and leaving the middle part open for horsemen and cattle. The bridge which joins the Chaur Bang with the suburb of Julpha, is 1000 feet long, and has thirty-four arches. The streets of Ispahan are narrow, winding, and irregular; and being quite unpaved, the wind, in dry weather, raises such clouds of dust, that the sun cannot be seen. Great pains are in consequence bestowed in watering the streets. The houses within, though they are handsome and convenient, have a mean appearance from the street, being built merely of bricks dried in the sun, and covered with flat roofs. The walls by which the city was formerly surrounded, are now entirely obliterated. They were merely built of mud dried in the sun, and were never able to offer any effectual resistance against a vigorous assault.

Ispahan, during its prosperity, was greatly distinguished by the extent and beauty of its suburbs. The suburb of Julpha was very wealthy and populous. It was chiefly inhabited by Armenians, who were transferred here from Old Julpha in Armenia, on account of their skill in manufacturing industry. They were soon joined by others of their countrymen, as well as by a number of Georgians, Circassians, and other Christians, the suburbs being appropriated to the professors of that faith. The streets are broad, with well built houses and a numerous population, with walks of trees, cooling fountains, and pleasant gardens. It is now reduced to a complete ruin. Its 10,000 inhabitants have diminished to 300 wretched families, dwindling every year both in respectability and numbers; its thirteen churches are reduced to two, and these dirty and dark and dismal in their appearance. The worship of the Guebres, the ancient worshippers of fire, and that of Abbas Adab, formerly very extensive, have quite disappeared.

Ispahan, after such a long period of misery and desolation from foreign wars and internal revolutions, has begun to revive from its low state, partly through the spontaneous efforts of its inhabitants, anxious to better their condition, and partly also through the exertions of Hajee Mahommed Hussein Khan, who, from the lowest situation, having acquired immense wealth, has employed it in the improvement of his native city and province. He has completed a royal palace, and has beautified and rebuilt many of the bazaars; repaired and added to the number of the fountains and aqueducts which supply the public gardens with water; and inclosed and cultivated all the waste land in the vicinity of the city, by planting rice fields, which are irrigated by the waters of the Zeinderood, and the cultivation of which is likely to supersede entirely its once abundant nurseries for cotton and silk. Ispahan has still very extensive manufactures. It excels in silk manufactures and in gold brocade; and it is also a great emporium of inland trade, and a depôt of Indian produce, being the chief medium of intercourse between India, Cabul, and the east, and Turkey, Egypt, and the countries round the Mediterranean, in the west. Lat. 32° 25′ N.; Long. 52° 50′ E.

ISPIRA, a town of Turkish Armenia, the ancient Hispiratis, now an inconsiderable town, but situated in a very fertile district, and surrounded by many fine and rich villages. It is ninety miles east of Trebisond.

ISRAEL, the name which the angel gave to Jacob, after having wrestled with him all night at Mahanaim or Penuel (Gen. xxxii. 1, 2, and 28, 29, 30, and Hosea xii. 3). It signifies "a conqueror of God," or "a prince of God," or, according to many of the ancients, "a man who sees God." By the name of Israel is sometimes understood the person of Jacob; sometimes the whole people of Israel, or the whole race of Jacob; and sometimes the kingdom of Israel, or of the ten tribes, distinct from the kingdom of Judah.

ISRAELITES, the descendants of Israel, who were at first called *Hebrews*, by reason of Abraham, who came from the other side of the Euphrates; and afterwards *Israelites*, from Israel the father of the twelve patriarchs; and, lastly, *Jews*, particularly after their return from the captivity of Babylon, because the tribe of Judah was then stronger and more numerous than the other tribes.

ISSACHAR, one of the divisions of Palestine by tribes, situated to the south of Zabulon, and by a narrow slip reaches the Jordan, between Zabulon and Manasseh (Joshua, xix). But whether it reached to the sea, is uncertain. Some hold that it did; but this is an assertion not easy to be proved, as Joshua makes no mention of the sea in this tribe, nor does Josephus extend it farther than to Mount Carmel; and in Joshua (xvii. 10) Asher is said to touch Manasseh on the north, which could not be if Issachar extended to the sea.

ISSENGEAUX, an arrondissement of the department of the Upper Loire in France, extending over 1200 square miles. It is divided into six cantons, and these into thirty-seven communes, which contain 76,306 inhabitants. The capital is a city of the same name, which contains 1050 houses, with 6571 inhabitants, who subsist chiefly by agricultural operations.

ISSIN, a small town of Persia, two miles north of Gombroon, to which many of the inhabitants of that city retire during the unhealthy season.

ISSOIRE, an arrondissement of the department of the Puy-de-Dôme in France, extending over 758 square miles, divided into nine cantons, composed of 116 communes, and inhabited by 95,500 persons. The capital is a city of the same name, situated on the river Crouse, which a little below falls into the Allier. It contains 730 houses and 5,479 inhabitants, who manufacture some jewellery. Lat. 45° 33′; Long. 3° 10′ E.

ISSOUDUN, an arrondissement of the department of the Indre in France, extending over 466 square miles, divided into four cantons, and those into fifty-three communes, and containing 39,887 inhabitants. The capital from which it takes the name, is a city which is situated on the river Theals, a second-rate stream. It is surrounded with ditches and walls, defended by towers, and contains 2050 houses, with 10,710 inhabitants. A great quantity of leather is cured in it, and there are many hats and stockings made. Lat. 46° 56′ 53″; Long. 1° 54′ 5″ E.

ISSUE, in common law, has various applications, being sometimes taken for the children begotten between a man and his wife; sometimes for profits growing from amercements or fines; sometimes for profits of lands and tenements; but more frequently for the point of matter depending in suit, upon which the parties join, and put their cause to the trial of the jury. In all these occasions, issue has but one signification, which is, an effect of a cause preceding; as the children are the effect of the marriage between the parents; the profits growing to the king or lord, from the punishment of any man's offence, are the effect of his transgression; and the point referred to the trial of twelve men is the effect of pleading, or process.

ISSURDU, a town of Hindostan, in the province of Asmeer, in the Rajpoot territories. It is surrounded with a wall and ditch, has a citadel in the centre, and is one of the best built towns in the province. Lat. 26° 26′ N.; Long. 76° 10′ E.

ISSUS, now Ajazo, a town of Cilicia in Natolia, with a harbour on the Levant sea, a little to the north of Scanderoon. Lat. 36° 56′ N.; Long. 36° 25′ E.

ISTAKHAR, a castle of Persia, formerly one of the citadels of Persepolis. It is situated on a very lofty and steep rock, and completely commands the surrounding plains. On the top is abundance of water.

ISTHMIA, or ISTHMIAN *Games*, one of the four solemn games which were celebrated every fifth year in Greece. They derived their name from the isthmus of Corinth, where they were celebrated. In their first institution, according to Pausanias, they consisted only of funeral rites and ceremonies in honour of Melicertes; but, as Plutarch informs us, Theseus, in emulation of Hercules, who had appointed games at Olympia in honour of Jupiter, afterwards dedicated these to Neptune, his reputed father, who was regarded as the partieular protector of the isthmus and commerce of Corinth. The same trials of skill were exhibited here as at the other three sacred games; particularly those of music and poetry. These games, in which the victors were only rewarded with garlands of pine leaves, were celebrated with great magnificence and splendour as long as Paganism continued to be the established religion of Greece; nor were they omitted even when Corinth was sacked and burned by Mummius the Roman general; at which time the care of them was transferred to the Sicyonians, but was again restored to the Corinthians when their city was rebuilt.

ISTHMUS, a narrow neck or slip of land, which connects two continents; or joins a peninsula to the terra firma, and separates two seas. The most celebrated isthmuses are that of Panama or Darien, which joins North and South America; that of Suez, which connects Asia and Africa; that of Corinth, which unites the Morea with Western Greece; that of Crim-Tartary, otherwise called *Taurica Chersonesus;* and that of the peninsula Romania, and Erisso, or the isthmus of the Thracian Chersonesus, twelve furlongs broad, being that which Xerxes undertook to cut through.

ISTRIA, a peninsula of Italy, in the territory of Venice, situated in the northern part of the Adriatic Sea. It is bounded by Carniola on the north; and on the south, east, and west, by the sea. It produces wine, oil, and pastures; and there are quarries of fine marble. One part of it belongs to the Venetians, and the other to the house of Austria. Capo d'Istria is the capital town.

ITALICA, in *Ancient Geography*, a town of Bætica in Spain, built by Scipio Africanus, and famous for being the birth-place of the emperors Trajan and Hadrian, and of the poet Silius Italicus. It is now *Seville Vieja*, a small village of Andalusia, on the Guadalquivir.

ITALY.

History.

This extensive and interesting portion of Europe did not receive the name it has long borne till the extension of the Roman empire. The origin of that name has been derived by different persons from various sources. Timæus and Varro have deduced it from a Greek word, Ιταλος, which signifies an *ox*, because it contains a vast extent of pasture land, peculiarly adapted to that animal. Thucydides and Dionysius of Halicarnassus derive the name from a king Italus. In early periods it was sometimes called Saturnia, from the name of a deity, Saturn, in the heathen mythology. It was sometimes called Œnotria, from a Sabine chief named Œnotrius; and frequently Ausonia, from Auson, a son of Ulysses, who is said to have established a tribe in the centre of the peninsula. All of these more ancient names seem, however, to have referred only to particular districts, which, when the Roman power had subjected them all, assumed, with the other parts subsequently united to them, the general name it still continues to bear. The Greeks at all times applied to it the name Hesperia, on account of its being to the westward from their country; and the Teutones or Germans called it Waelschland, because the parts nearest to them were inhabited by a people called Galles, changed into Walles; and in their present language the name of Waelschland is still retained by the common people.

The history of Italy before the rise of the Roman power is, like that of all rude nations, involved in obscurity, or clouded with indistinctness; through which the indefatigable Niebuhr, with a profusion of learning, has endeavoured to grope his way. Before Rome began to be powerful, Italy was peopled by inhabitants who had made some advances towards civilization. In the northern part the Gauls were rude and fierce, and they the longest resisted the encroaching power; whilst lower down, on the Arno and the Tiber, there was a number of smaller tribes, such as the Etruscans, the Samnites, and the Latins, who, in a kind of confederacy, though sometimes at variance with one another, long sought, and ultimately in vain, to defend their freedom against the rising and aspiring city. In the southern parts were colonies of emigrants from Greece, with but little union, and frequently engaged in hostilities amongst themselves. When and by what means all these tribes became finally subjected to Rome, belongs to the history of that empire; for the history of the conquered is swallowed up in that of the conquerors.

A. D. 476 to 568.

The fate of Italy was that of Rome till the dissolution of that colossal power. When the seat of empire was removed to Constantinople, Italy, though accounted a portion of the western empire, was treated as a dependent province, and continued with only the semblance of power, which power was finally wrested from all dependence on Byzantium by an adventurous Gothic warrior, who, about the year 476 of the Christian era, founded the kingdom of Italy.

Odoacer had raised himself, by his intrigues amongst the mercenary guards, to the command of those troops, who from inactivity had become restless and mutinous. Augustulus, the last emperor of the West, was unable to resist the power of his disaffected troops, and withdrew to Pavia. That city was besieged, captured, and ravaged, and Augustulus retired to obscurity, when Odoacer proclaimed himself king of Italy. He exercised the power with dignity, and, as regarded Augustulus, with clemency, by assigning him a liberal establishment, during the few years that remained of his life, in the retreat he had selected in Campania. Italy was in a wretched state, and Odoacer used as much prudence and humanity as could have been exercised by a rude conqueror, to improve the condition and the institutions of the country; but the licentious troops who had been the means of his obtaining it could not be kept in obedience by a power so created, and disorders became universal. When Odoacer had reigned fourteen years, Theodoric, king of the Ostrogoths, at the instigation of the Emperor Zeno, who reigned in Byzantium, invaded the newly-founded kingdom; defeated and assassinated Odoacer; and, in 493, added the whole of Italy to his dominions, which thus extended from the Alps to Sicily. The only part not subjected was some islands in the lagunes of the Adriatic Sea, inhabited by fishermen and salt-makers, who had first found a refuge in these from the ravages of Attila, and had there secured freedom, and by their union, and by the capability of defending themselves, laid the foundation of what subsequently became the republic of Venice. In the favoured climate of Italy, and under the government of Theodoric, the Goths multiplied rapidly; and they were almost the sole masters of the soil, and of the slaves who cultivated it. By his external policy he had acquired the confidence of the other Gothic tribes, even in the remote regions that border on the Baltic Sea, and had introduced strong and regular forms of government into Rhætia, Noricum, Dalmatia, and Pannonia. Though the jealousy of the emperor at Byzantium induced him to invade the territory commanded by Theodoric, and to employ both a large fleet and a powerful army, his attempts were repelled by sea and by land, and his forces were dispersed or dispirited, and retired from the contest.

Theodoric was not less successful in another attack from the west by King Clovis, the leader of the Franks, who were checked in the midst of a career which had commenced with brilliant success.

Ravenna was the seat of the government of this prince, though he occasionally resided at Verona. He once visited Rome, where he was received with rapture by the populace, and with the highest marks of respect by the senators. During the latter and peaceful portion of his reign he endeavoured to amalgamate his Italian and Gothic subjects; but his success was much obstructed by the religious controversy between the orthodox and the Arians, though, whilst adhering to the latter sect, he tolerated and even honoured many of the other profession. But a union was in some measure effected between the conquerors and the conquered, and civilization was advanced during this long reign, although at the sacrifice of the manly simplicity of the former to the corruption and luxurious indulgences of the latter.

Theodoric died in the palace he had built at Ravenna, in 526, after a reign of thirty-three years, having by his will divided his dominions between two grandsons, bequeathing Italy to Athalaric, then a boy of twelve years of age. The youthful sovereign was left under the pupillage of his mother Amalasontha, from which he was early withdrawn by the flatterers who surrounded him. His mother then entered into intrigues with the Emperor Justinian, tending to deliver up Italy to its ancient dependence on the court of Byzantium. Her son, as he advanced in age, entered on the most dissolute courses, by which his life was terminated in the sixteenth year of his age. His mother, who assumed the power, was speedily assassinated by a husband she had chosen to be a sharer of the throne.

The imperial court was eager to take advantage of the unsettled state of Italy to reduce it again under subjection. Belisarius, the most renowned of the generals, was despatched, but with an inconsiderable force. Hostilities raged with great fury, and after a variety of changes in the aspect of affairs, the imperial commander had so weakened the Goths, and so engaged the confidence and assistance of the Italian inhabitants, that the prospect of complete subjugation presented itself. This was, however, clouded by the dissensions which broke out amongst the officers in command of the several divisions of the army of Justinian in 538. At that time the chief command was conferred on Narses, a eunuch, whose conduct at that period, whatever military merit he afterwards displayed, tended greatly to the injury of his sovereign's party.

Narses was indeed soon recalled, and Belisarius reinstated in the supreme command; but in the midst of discord the Goths had been permitted to breathe, an important season was lost, Milan had been destroyed, and the northern provinces of Italy were afflicted by an inundation of the Franks. Under Belisarius the events of the war underwent a favourable change; he captured the strongly fortified city of Ravenna, and returned with numerous captives to Constantinople to receive the applause of the people and a splendid triumph, the last reward of his valour and his humanity.

The removal of Belisarius from Italy revived the spirits of the remaining Goths, and the feeble efforts of the successive generals of Justinian were insufficient to crush the civil war. The handful of the barbarians, scarcely amounting to five thousand, and in possession of no other strong place than Pavia, chose Totila for their chief, and proclaimed him king of Italy, in the year 541.

His progress was rapid, and almost without interruption, from the north of Italy to Naples. He captured that city, and returned to Rome, which he besieged; and though Belisarius, who had been recalled from the wars of Persia, attempted to relieve it, he was unable to do so; and the citizens, compelled by famine, allowed the Goths to occupy the capital of the western empire in the year 546. After an useless occupation of Rome when it had been abandoned by Totila, Belisarius was recalled to Constantinople, and the command once more conferred upon Narses, who was furnished with troops, stores, and money, with a profusion widely different from the parsimony exercised towards his predecessor. He advanced with his forces by the head of the Adriatic Sea, and in a tremendous battle encountered the Goths under Totila, whom he totally defeated, whilst that chief was killed in the conflict. After his death, those who had escaped elected Tejas as their king; but he too became the victim of his ambition, was soon subdued by Narses, and with him terminated, in 553, the Gothic kingdom of Italy, by the capture of the last of their fortified places.

Italy, after these events, became once more a province of the Roman empire, of which Ravenna formed the capital, and in which the representatives of the emperor, the exarchs, fixed their residence. Narses, the first of them, was removed by the jealousy of the Byzantine court; and his successors neglected the defence of the Alpine passes, by which the Longobards, or Lombards, a German race, entered the country. They are supposed to have been of Scandinavian origin, and to have gained a settlement between the Oder and the Elbe in the reign of Augustus. They gradually descended towards the south, and approached the Danube. At the solicitation of Justinian, they passed that river, to reduce, in pursuance of a treaty, the cities of Noricum and the fortresses of Pannonia; but the spirit of rapine soon tempted them beyond these limits, and at length, under Alboin, in 568, they penetrated into Italy.

Before the Lombards entered Italy, they were established on the frontiers of the Roman empire, and had for neighbours two other barbarous tribes, the Avars and the Gepidæ, who were sometimes hostile towards each other, though commonly at peace, demanding and receiving what they deemed tribute, but what the imperialists in their weak state denominated presents. The Avars and the Lombards, at the instigation or with the connivance of the Emperor Justin, the successor of Justinian, jointly attacked the Gepidæ. The bravest of them fell in battle; their king Cunimund was slain, and his daughter Rosamund became the captive of Alboin, the chief of the Lombards, and by marriage shared that throne which had before been occupied by the daughter of Clovis, the king of the Franks.

The ambition of Alboin was excited rather than satisfied by the conquest of the Gepidæ, and the submission of the Avars to his authority; and he turned his eyes from the Danube to the richer banks of the Po and the Tiber. Fifteen years before, his subjects, as the confederates of Narses, had visited Italy; the mountains, the rivers, and the highways, were familiar to their memory. The report of their success, and the views of the spoil, kindled in the rising generation the flame of emulation and of enterprise. Their hopes were encouraged by the spirit and eloquence of their leader. No sooner had Alboin, or Alboinus, erected his standard, than the native strength of the Lombards was multiplied by the adventurous youth of Germany and Scythia. The robust peasantry of Noricum and Pannonia resumed the manners of barbarians; and the names of the Gepidæ, as well as of the Bulgarians, the Sarmatians, and the Sueves, are now to be found in the provinces of Italy. It has been said that Narses the eunuch, to resent an affront offered him by the Empress Sophia, the wife of Justin, had instigated Alboin to the attempt, and counselled him to form an alliance with the Huns before he commenced his operations.

The whole nation of the Lombards, accompanied by their allies, and attended by their wives, their children, their cattle, and their most valuable effects, began their march in April 568. They had no opposition to encounter as they passed through the Venetian country, and the city of Aquileia opened its gates, most of the inhabitants having abandoned their homes at the approach of the formidable invaders. Alboin passed the winter in Friuli, with his troops quartered around him, which city he erected into a dukedom, and appointed his nephew Gisulphus to govern and watch over the territory. In the succeeding year the conqueror advanced and occupied Trevigio, Oderzo, Vicenza, Verona, and Trent, leaving in each city a garrison, and intrusting the whole to one of his officers, with the title of duke during his command. Padua and some other cities were passed by, either because they did not intercept his progress, or because they were too strongly garrisoned. In the third campaign Alboin passed into Northern Liguria, and possessed himself of Brescia, Bergamo, Lodi, and Como, with little opposition, the inhabitants having escaped to the mountains. Milan, then the capital of Liguria, was captured after a short siege, the principal people, with their bishop, Honoratus, having fled to Genoa. In Milan the ceremony of the inauguration was solemnly performed. Alboin was lifted on a shield in the midst of his troops, received the emblems of royalty then in use, and was proclaimed king of Italy.

From Milan Alboin sent out expeditions, which reduced Piacenza, Parma, and Modena, and the other inland cities in Æmilia and Tuscany. At Pavia he met an obstinate resistance, but, after a siege which endured more than three years, that city at length surrendered; and being strongly fortified, it was fixed as his place of residence, and long continued to be the capital of the Lombard kingdom. Whilst Alboin was in Pavia taking the steps necessary to defend the dominions he had acquired, and to reconcile his new subjects to his rule, he was murdered at the instigation of his wife, in the palace at Pavia, in the year 575. The queen, with her paramour, made an attempt to obtain the command of the Lombards; but not succeeding in their purpose, they fled to the Roman garrison at Ravenna, where both perished most miserably. Clephis, a relation of Alboin, having been raised to the throne, extended the Lombard power to the gates of Rome; but he conducted himself with such cruelty, that he was killed by his own people, after a reign of less than a year. His actions produced a dislike to monarchical power, and for ten years no king was chosen. The dukes who had been created among the chiefs of the Lombards acted in their respective territories as independent but allied sovereigns. Under this kind of government their power continued to extend, and that of the emperor gradually retreated before it. The want of a central authority was, however, soon discovered; and, in 586, Autharis, the son of Clephis, was chosen as king, and, by his valour and prudence, established the throne so securely, that it continued to flourish through the two succeeding centuries. It is not necessary to enter into a minute history of the several kings of Lombardy who ascended the throne of that country. A kind of aristocratic monarchy was created, composed of thirty principalities, the chiefs of which were distinguished by the titles of dukes, counts, or barons, which, with the revenues of the land, were held as fiefs under the kings, and became gradually hereditary. The islands of the Adriatic were formed into a republic, and the inhabitants, by electing, in 697, their first doge or duke, formed an independent and central government. The exarch appointed by the government at Constantinople held authority at the city of Ravenna, and had under his power Romagna, the Pentapolis, or five maritime cities of Rimini, Pesaro, Fano, Senigaglia, and Ancona, and almost the whole sea-shores of Lower Italy, where Amalfi and Gæta had their own dukes of the Greek nation. The island of Sicily, and the capital, Rome, in which a patrician ruled in the name of the emperor, formed also parts of the imperial dominions.

Constantly pressed upon by the Lombards, the power and influence of Constantinople gradually declined; and its fall was hastened by the Emperor Leo, called the Isaurian, whose zeal in the destruction of images embittered the clergy of the orthodox church in Italy. The inhabitants of cities forcibly expelled the imperial authorities, and elected a senate, with consuls, as in the time of the Roman republic. In Rome itself a certain power was acknowledged in the bishop, which, on account of the sanctity of his character, was of a paternal nature; at first it was exercised in ecclesiastical affairs, but by degrees extended to civil matters, and in process of time arrived at temporal sovereignty. The popes, who were anxious to defend their territory against the Lombards, when the Byzantine court had neglected or abandoned them, applied for assistance to the Franks.

It may not be improper here to remark, that the original Lombard invaders, composed as they were of various tribes, comprised different religions, some of them still adhering to the ancient heathenism, either of the Greek or the Gothic description; whilst others had embraced the Christian religion, but with the heretical tenets of Arianism. These tribes, with little attention or little adherence to any doctrinal points, had gradually been led to embrace the profession of the Roman Catholic church. Luitprand, who ascended the throne of Lombardy in 711, was the last of that nation to abandon his heresies, which he did in the presence of Pope Gregory at Rome in 729; upon which the pontiff made a public renunciation of his allegiance to the imperial court, and withdrew all claim of obedience from it. Gregory was, however, indisposed to form an alliance with Luitprand, whose vicinity to the capital of his diocese he viewed with suspicion. When the emperor was making preparations to invade Italy, in order to enforce his decrees for the destruction of images, the pope addressed himself to the Frankish monarch, then one of the most powerful princes of western Europe.

The Franks were at that time governed by the celebrated Charles Martel, who had highly distinguished himself in war, and was considered as the best commander of his time. Gregory despatched an embassy to his residence, with numerous presents of holy relics. It was received with respectful distinction, and a treaty was speedily concluded, by which Charles engaged to march with an army into Italy in defence of Rome and of the church, in case any attack should be made by the emperor or the king of Lombardy. The Romans, on their part, were to acknowledge Charles as their protector, and to confer upon him the dignity of the consulship.

Leo the Isaurian was succeeded by his son Constantine surnamed Copronymus, who carried his rage against images to a greater extent than his predecessor, and forbade the worship of the saints and of the Virgin Mary. This occasioned new disturbances in Italy, and made the Romans more zealous than before to separate themselves from their dependence on Constantinople. Zachary, who had succeeded to the chair of St Peter, urged on Luitprand the restoration of the four cities, and also the district of Sabina, which had been seized upon thirty years before; and in compliance with the representation, they were thus added to the sacred patrimony. Luitprand died in 743, after a reign of thirty-two years. His son Rachis, who succeeded him, was anxious to extend his dominions, and invaded the territory ceded to the holy see by his father, when Pope Zachary visited him, and, by his representation of the punishment hereafter to be inflicted on those who violated the rights of the church, so operated upon his mind, that he not only restored the towns and territory he had seized, but took the habit of a monk, and entered into the monastery of Monte Cassino, where he passed the remainder of his days, honoured as a saint by the other monks of the fraternity.

Astulphus succeeded his father on the Lombard throne in 751. The exarchate of Ravenna and the duchy of Rome excited his love for conquest. The city, the capital of the first, was surrendered with little difficulty. He advanced towards Rome, and, when arrived at Narni, sent an embassy to the pope, announcing his determination to enter that city, to seize the wealth of the Romans, and to impose a tax of a golden solidus on every one who would not swear allegiance to the Lombard throne. Stephen, who then filled the papal chair, attempted by negotiation to avert the threatened storm; but failing to appease Astulphus, in imitation of his predecessor, he had recourse to the assistance of France. Pepin, the son of Charles Martel, now filled the throne of that kingdom, and professed unlimited obedience to the holy see. Stephen, by the consent, or at least connivance, of Astulphus, whose forces were encamped round the city of Rome, made a journey to France, and Pepin immediately, accompanied by the pope, passed the Alps with a large army, and advanced into Italy. Astulphus could not raise a sufficient force to repulse his assailants, and, after some slight reverses, retired to Pavia. In that city he was besieged, and compelled to sue for peace. This was granted, upon the condition that he should give up, not to the emperor, but to the pope, the several cities he had captured in the exarchate and the dukedom, and deliver hostages for the performance of the conditions agreed on. Pepin with his forces returned to France; and the pope proceeded with exultation to the south, in the expectation of being placed in possession of the cities and territories which Astulphus had stipulated to deliver up, and which Pepin had guaranteed to the holy see. The Lombard king, however, as soon as the storm had passed over, broke into the dukedom and besieged Rome. The pope again had recourse to Pepin, who readily advanced. Astulphus, after an unavailing siege of three months, abandoned Rome, and once more took refuge in the strong fortifications of Pavia. During this second siege, which Pepin speedily commenced, an embassy from the Emperor Constantine Copronymus arrived at his camp, to remonstrate against the donation of the exarchate to the pope; and offered to repay the expenses of the war to France, if the territories were delivered over to the power of the emperor. Pepin replied to the envoys, that "as he had a right to those territories by the sword, and had thought proper to bestow them on the pope, nothing should induce him to alter his resolution." By a vigorous prosecution of the war, Pepin obtained a peace; and for the pope the city of Commachio, in addition to what had been before ceded to him. From this period, 756, the pontiffs assumed the language as well as the power of sovereigns, no longer using for the dates of their rescripts the year of the reign of the emperor, but that of their own pontificates.

Astulphus, soon after executing the treaty concluded at Pavia, met an untimely death, the manner of which, however, has been variously described. During the succeeding twenty years the Lombards languished in a state of weakness and decay, but interrupted by a disputed succession, which ended in the elevation of Desiderius to the vacant throne. A double marriage was arranged between two daughters of this Lombard king and Carloman and Charles (usually called Charlemagne), the sons of Pepin. Charles soon divorced his wife, under the pretence of barrenness; and Carloman died, leaving two sons, the grandsons of Desiderius, who detained them in the hope that they might be made use of to produce disturbances in France. Thus family jealousy was one amongst many grounds of quarrel. Desiderius was induced to attack the dominions granted to the pope; and, at the invitation of the pontiff, Charlemagne advanced with a large army. Desiderius, like his father, took refuge in Pavia; and after the capture of Verona, and a visit to Rome, Charlemagne drew up his forces, a part of which had blockaded it, around that city. The defence was brave and protracted; but by famine, and by the plague, which raged within the walls, the city was at length compelled to surrender. Desiderius being thus made prisoner, and sent with his family to France, all the other cities submitted to Charlemagne in 774. That monarch claimed the kingdom of the Lombards by right of conquest, and caused himself to be crowned king, with an iron crown, by the hands of the Archbishop of Milan, in the presence of his army, at a place called Modastia, about twelve miles from that city.

Thus ended the kingdom of Lombardy, after it had existed two hundred and six years. Though the Lombard kings were at first rude and barbarous, yet, when they had embraced the Christian religion, they ruled with great equity and mildness. "Under their government," says Paulus Diaconus, "no violence was committed, no one unjustly dispossessed of his property, none oppressed with taxes; theft, robberies, murder, and adultery, were seldom heard of, and every one went whither he pleased. They were the only power in Italy capable of defeating the ambitious views of the bishops of Rome, and hence arose the inveterate hatred which the popes bore to them; but their many wholesome laws, which are still extant, are at the same time convincing proofs of their justice, humanity, and wisdom, and a full confutation, as Grotius observes, of the many calumnies with which the popes and their partisans have endeavoured to asperse them."

The conduct of Charlemagne to his newly-acquired kingdom appears to have been wise and liberal. He sanctioned the laws by which the districts had been governed, whether Roman or Lombard; but to the latter he made a few additions. The emperor was left in quiet possession of the dukedom of Naples, and of the other places in Italy that he held. He allowed to the Dukes of Spoleto, Friuli, and Benevento, the same power and authority as they had exercised under the Lombard kings; and the smaller dukes were continued in their dignities, but were compelled to take annually the oaths of allegiance to him; and, unless they violated it, the dignity was made hereditary in their families. Having thus settled the affairs of Italy, he returned to France, having, in 781, appointed his son Pepin his viceroy.

A seditious controversy in Rome, respecting the election of a pope, induced Leo III. who had been raised to that dignity, to pass the Alps and apply for protection to Charlemagne, against the Roman populace. The conqueror of Italy, in consequence of this, repaired to Rome, where, on Christmas day 800, during the celebration of divine rites, Leo suddenly placed a valuable crown on his head, and the church resounded with the acclamations of the people, "Long life and victory to Charles, the most pious Augustus, crowned by God, the great and pacific emperor of the Romans." The title thus conferred by the pretended sudden impulse of a pope, on a conqueror who denied all participation in the project, has been retained by his German successors, till it was abandoned in the present century, out of compliment to revolutionary France.

A. D. 774 to 961.

During the life of Charlemagne, whilst his son Pepin was acting as viceroy, Venice, which had grown up to be a consolidated and warlike power, disavowed the title conferred by the pope, and commenced hostilities against his Italian dominions. The Saracens, a new power, availed themselves of the circumstances, and attacked the islands of Corsica and Sardinia, where they obtained much plunder, and made many of the inhabitants captives. Pepin equipped an army and a fleet to reduce Venice to submission; but having failed in the attempt, and lost most of his vessels among the shoals and rocks of the islands, chagrin at the reverses he sustained caused his death, which took place soon afterwards at Milan. A natural son of Pepin, named Bernard, was nominated by Charlemagne as his viceroy in Italy.

Charlemagne died in 813, and was succeeded by his son Louis. Louis and Bernard met at Aix-la-Chapelle, and appeared to have arranged the mode of ruling the extensive dominions of their departed ancestor; but the ambition of Bernard led him to attack his uncle, and to dispute his succession. Louis, however, was enabled to baffle his aspiring nephew, who was defeated, captured, and condemned to the loss of sight, under which operation he expired, in the fifth year of his reign.

Italy remained as a portion of the Frankish monarchy till the treaty of Verdun in 843, when it was delivered over, with the imperial title, and with the addition of the country of Lorraine, to Lotharius I. the eldest son of Louis. He bequeathed his dominion to Louis II. in 850, who appears to have been the best of the princes of the Carlovignian race. He died, after a prosperous but rather a turbulent reign, in 875. The election of a pope, Benedict III. his rejection by Louis, and the ultimate submission of the monarch to its legality, were sources of vexation, though not of actual hostility. In the latter years of his reign, the Saracens, instigated by the emperor, invaded the south of Italy; but having been defeated near Capua, they were expelled the country. Three years afterwards they again resumed their attacks, and besieged Salerno; but meeting with a severe repulse, they again departed, leaving Italy at peace at the time of the death of the monarch.

His death seemed the signal for discord, from the va-

History.

rious claimants in the imperial family to the Italian dominions. Charles the Bald of France first took possession; but dying in 877, Carloman, king of Bavaria, seized the inheritance; and he was followed in 880 by his brother Charles the Fat, king of Suabia, who, for the last time, united under one sovereign the whole of the Frankish monarchy. During seven years Italy was the theatre of lawless violence, in which the nobles required an Italian prince, and the pope was anxious to have a foreigner placed on the throne; whilst the Saracens, availing themselves of the disturbances, extorted money from the pope as the price of peace, and still continued their depredations. Berengar duke of Friuli, and Guido duke of Spoleto, with the Marquis of Ivrea, were rivals for the throne; but Guido was, in 894, crowned as emperor and king, and his son Lambert nominated as his successor in these dignities. Arnulf, the German king of the Carlovignian race, urged and succeeded in his pretensions, and was crowned in 896; but, like those who succeeded him, he was unable to exercise any considerable power except whilst he continued to reside among his subjects.

After the death of Lambert in 898, and of Arnulf in 899, Louis, king of Lower Burgundy, appeared as the rival of Berengar I., but without effect; and the same fate befell another claimant, Rudolph of Upper Burgundy; in spite of the pretensions of both, the possession of the throne was at length, in 915, in the hands of Berengar, who was solemnly crowned. The power in the hands of the feudal vassals of the throne was so much weakened by the recent dissensions, that it became almost impossible to repress the plundering inroads which the Saracens were continually making on his dominions. This monarch was murdered in 924, when Rudolph of Upper Burgundy was induced to transfer his pretensions to the throne to Hugo, count of Provence. Hugo endavoured, by the exercise of the most bloody tyranny, to gain the unsteady dominion of Italy; but his nephew Berengar, marquis of Ivrea, having escaped some snares that were laid for him, fled for refuge to Otho the Great, in Germany, collected there a number of fugitives, turned towards Italy, and in 945 succeeded in compelling Hugo to abdicate the throne, and transfer it to his son Lotharius, who was less the object of general aversion than himself, and who, upon his accession, appointed Berengar his first minister of state.

The death of Lotharius occurred in 950, and was supposed to have been the result of poison administered by Berengar, who was desirous to force the beautiful wife of the former to unite with his son. To avoid this match, and to escape from the consequences of rejecting it, she fled for safety to the city of Canosa, against which her persecutor commenced a siege. She then applied for assistance to King Otho. He with great expedition passed the Alps, liberated the lady, defeated Berengar, captured Pavia, and having seated himself on the throne of Italy, espoused the fair Adelheld in 951. Berengar made himself useful to the new sovereign by his early submission, and by his delivering up the Friouls, the keys of Italy, to the brother of Otho; and thence his offers of service were accepted, and he was appointed to rule the country in the name of Otho. After ten years, complaints reached the throne from the great vassals in Italy, when Otho returned there, dismissed Berengar from his station, led him as a prisoner to Bamberg in Germany, and having united Italy with his German dominions, was crowned with the iron crown at Milan in the year 961. Otho certainly granted the best lands as feuds to his German nobles; but he conferred great privileges on the cities of Italy, and on these were grounded free constitutions, which, however, soon converted the country into a theatre of anarchy. During the tenth century, the liberality of the Frankish kings, who had served their purpose, so corrupted the church, and so weakened the royal authority, that it effectively undermined it; whilst the clergy and the people elected the popes according to the dictation of the consuls and of the inferior patricians. Thus it happened that, in the first half of the tenth century, two eminent intriguing females disposed of the holy see. Theodora, in 914, raised her son by her lover Pope John X., to the chair of St Peter, which he filled under the name of John XI. The brother of the last, Alberich of Camerino, and his son Octavian, were absolute masters of Rome; and the latter was consecrated pope in 956, at the age of twenty years. Otho, when crowned at Rome in 962, annulled the election, and appointed Leo VIII. in his stead; but the people, jealous of this exercise of power, elected Benedict V. The popes, instead of governing Rome, were thus themselves dependent on the leaders of the populace.

The republics of Gaeta and Amalfi, in the Neapolitan part of Italy, still maintained their independence against the Lombard dukedom of Benevento. This was more easily defended, from a division having been made of the territory of the dukedom, which diminished its power, and because they had a common enemy to contend with in the Saracens, who had by each party been invited to afford them assistance in their quarrels, but who had fixed themselves in Apulia, and there constructed powerful fortifications. The Emperor Louis II. and King Macedo, by their united forces, had so broken the power of the Mussulmans in 866, that the latter could no longer maintain themselves in Lower Italy; and thus enabled the Greeks to form establishments on the territory previously occupied by the Saracens. They founded a province, called the Thema of Lombardy, which was ruled by a chief residing in Bari, and which maintained its independence during more than a hundred years.

Otho the Great was succeeded, in 973, by his son Otho II. Under his reign Crescentius, then consul in Rome, on the pretence of restoring the ancient constitution, attempted to secure to himself the sole power of that city; whilst Otho was occupied in carrying on some plans of conquest in Lower Italy, and suffered the vicious popes, Boniface VII. and John XV. to exercise supreme authority. But, in 983, Otho III. succeeded his father, and elevated his cousin Gregory V. to the papal throne, when Crescentius, with the assistance of the populace, was enabled to drive him from the city, and to fill his station with a Greek pope, John XVI.; and he attempted also to lead back the Romans to an apparent subjection to the Greek emperor. Otho soon replaced Pope Gregory in the papal chair by force, and besieged Crescentius in the Castle of St Angelo, where he was at length, with twelve others of his associates, made prisoner, and, along with them, suffered decapitation in 998. Though compelled to take the oaths of allegiance, the submission of the city was reluctant, and the disposition to throw it off was only repressed by force of arms.

A. D. 961 to 1073.

The death of Otho III. in 1002 was deemed by the Italians a dissolution of their connection with the German emperors, and Hardouin, marquis of Ivrea, was crowned king of Italy in Pavia; upon which the jealousy of the Milanese, the habitual rivals and enemies of Pavia, induced the citizens of that place to declare Henry II. of Germany as king also. The immediate consequence was a civil war, in which each city and district took a greater or a less part, and all suffered most severely. Henry was indeed, in 1004, acknowledged by the assembly of nobles collected in Pavia; but, in the tumult which arose on the occasion, a great part of the city was destroyed by fire.

After the death of Hardouin in 1015, Henry was acknowledged as king by the whole of Lombardy; as was also, after his death, his son Conrad II. who was, however, known in Italy as Italus or Italicus I. A general assembly was held near Piacenza, at which all the power of the feudatories was declared to be hereditary by an irreversible law, and zealous attempts were made to obtain peace and security to all the states. These efforts were ineffectual, from the rage between the growing cities and their bishops, as well as the hatred between the clergy and the nobles, and between those bodies and the inferior inhabitants. In republican Rome, where the family of Crescentius still directed the voices of the public, neither Henry, nor Conrad, nor the pope, could enforce obedience. When Henry III. the son of Conrad, came to Italy in 1046, he found no less than three popes in Rome. These he displaced, and selected, by his sole power, Clement II. who was placed in the chair of St Peter; and regularly afterwards raised to the spiritual dignities respectable German ecclesiastics. This reform, although apparently wise at the time, as giving dignity to the pontiffs, was afterwards found in practice to have tended to corrupt them.

During the long minority of Henry IV. after the death of his father, Hildebrand, a monk, afterwards Pope Gregory VII. took the lead in opposition to the temporal power, and increased that of the ecclesiastical to an alarming extent. This increase of clerical power was much promoted by the transactions of the Normans. As early as the year 1016, some warriors from Normandy settled in Apulia and Calabria, and having early formed alliances with the Lombards, the republics, or the Greeks, as best served their purpose, against the Saracens, they became, through their warlike habits, a very powerful party. Leo IX. made several attempts to draw them away; but these all failed, and ended in his own captivity and submission. Nicholas II. on the other hand, formed alliances with the Norman leaders, and in 1059 endowed Robert Guiscard with the feudal rights of all the lands he had conquered in Lower Italy. Afterwards, the popes, in the contentions with the imperial power, trusted chiefly to the aid they could draw from their faithful confederates, the newly-created Dukes of Apulia and Calabria, to whom were afterwards added the chiefs of the Normans in the island of Sicily. Whilst, in the south of Italy, the small states thus became larger, in the north the great states were broken up into several of small extent and power. The Lombard states founded their subsequent greatness, and Venice, Genoa, and Pisa had already become rich and powerful. The Pisans, who, in 980, were in alliance with Otho II. and performed great services against the Greeks, and against the Saracens in Lower Italy, united with the Genoese, now a seafaring and warlike people, to attack the unbelievers in Sardinia, and twice, in 1017 and 1050, conquered those intruders, and finally divided the lands, in large districts, amongst the most eminent of the native inhabitants.

A. D. 1073 to 1100. Gregory VII., usually called Gregory the Great, was at the head of the church, using all the exertions and influence of his station to extend its power. He laid claims to authority over Spain as a fief of the church, and required of that kingdom all the conquests which had been made from the Moors. Sardinia was demanded of the conquerors, and France was under his authority. He made attempts to exercise his power in Hungary, and even in Russia; and extorted from England the tax known by the name of Peter's pence, which long continued to be paid. In Italy, where knowledge had begun to dawn, there were many opposed to the vast extension of the papal power; but they were outnumbered by others, who feared more the government of a German prince. In most of the other parts of Europe the regular priests had so much influence, that the monstrous pretensions of the pontiff were submitted to with little or no reluctance. It was not so, however, in Germany. The policy of Gregory had enjoined on the priests the observance of celibacy, and the German clergy were reluctant to put away their wives. They opposed the pope's decrees, and joined with the emperor in resisting them. The German bishops in council pronounced the deposition of the pope; and the pontiff issued his excommunications against them and their emperor. A war thus broke out between Henry of Suabia and Pope Gregory, though Clement III. had been created pope by the Germans. Gregory and his army was defeated, and he retired to the Castle of Angelo, where he was long besieged, and at length, being released by Robert the Norman, removed to Salerno, where he died in the year 1085. Two popes were chosen in succession by the cardinals, viz. Victor III. and Urban II.; whilst the antipope Clement, with his conclave, sometimes in Rome, at other times driven from it, never ceased to fulminate his excommunications. Urban maintained the contest with Clement, and in fact triumphed over him. His success was owing in a great measure to the part he took in favour of the Crusades, which about that period began to excite the attention and rouse the passions of all Europe to achieve the conquest of the Holy Land. The enthusiasm of the period enabled Urban to drive Clement from the city of Rome, and to take possession of the chair of St Peter, in which dignity he terminated his life in the year 1099. Paschal II. was fixed by the cardinals at Rome in the papal chair; and though the party of Clement on his death elected another antipope, it did not weaken the secure hold on the dignity to which Paschal had been elevated. The son of Henry IV. was encouraged by the pope to rebel against him, as one who, being excommunicated, could not convey to his successor any right. The father was made prisoner by the son, and Henry V. was then crowned emperor and king.

Henry V., though, until he obtained the throne, the devoted defender of the papal claims, after his accession became their antagonist, and thus gained the support of his German nobles. After suppressing commotions in other parts of his dominions, he crossed the Alps with an army of eighty thousand men; passed through Italy to Rome without serious opposition; and there massacred many of the citizens, shut up the pope, the cardinals, and the nobility in prison, and held them confined till he had obtained from the pontiff the full investiture of all his dominions. The pope then crowned him as emperor, and honoured him at his departure with every mark of respect. Henry had scarcely reached his patrimonial dominions when he found a general flame kindled around him. The Lateran council disavowed all that his holiness had done, upon the notorious ground that it had been extorted by force. The French clergy had acquiesced in the excommunication, and those of Germany rejected the bull of investiture; whilst a rebellion, excited by Duke Lothario, broke out in Saxony. By the aid of the Duke of Stauffen-Suabia, Henry was enabled to lull the domestic threatening storm, and again with an army marched to Italy, and seized upon Rome, whilst the pope fled to Apulia. He was once more crowned, the ceremony being performed by the Archbishop of Braga, in Portugal, on the assumption that the former coronation had been invalid, from the perjury of the pope who had performed the ceremony. At the conclusion of his reign Henry V. had nearly lost his influence in Rome, so that he had, at least tacitly, given up all concern in the election of a pope, when Calixtus was chosen by one party, and Honorius II. by another, to fill that dignity. Shortly afterwards he died at Utrecht in May 1125.

During the reigns of these German princes many of the cities of Italy had risen to considerable wealth, power, and splendour, and, from the emperors being often absent with their armies in the other parts of their dominions, had assumed to themselves almost all the rights of sovereignty.

These cities forced the others of less extent near to them into an alliance, by which they obtained the aid of their population whenever they had occasion to have recourse to arms. The two cities of Milan and Pavia, in the north of Italy, were the chiefs of rival associations. Disputes between Milan and Cremona gave occasion to the first hostilities between the former of those cities and Pavia, in 1129, to which a contest between two rivals for the crown of Italy, Lothario II. and Conrad of Hohenstauffen, gave a different direction, and created two parties, the Guelphs, the adherents of the popes, and the Ghibelines, the supporters of the German emperors. These two parties, which long divided Italy, derive their origin from a family which in the eleventh century held extensive possessions in the north of Italy, amongst the mountains between St Gothard and the Brenner, and bore the name of Welf. They descended into the plains of Germany, and obtaining settlements in some of its finest provinces in the south of that country, this enabled them in process of time to become the founders of both the royal and ducal houses of Guelph; the first seated on the throne of Great Britain, and the second enjoying the duchy of Brunswick.

This family quarrelled among themselves, one branch bearing the name of Welf, changed by the Italians into Guelph, and the other Waiblingen, changed into Ghibeline; and they had, before their intermeddling in the Italian wars, fought a bloody battle at Winsberg in 1140. The state of Italy favoured the creation of parties, to which the chiefs of the two branches of this German family attached themselves, and continued their animosity during more than one hundred years.

In Rome were violent schisms between the partisans of rival popes; and this again gave rise to that spirit of independence which that city had constantly nourished. It was especially excited by the preaching of Arnold of Brescia, an eloquent monk, the pupil of Abelard, who declaimed with great energy against the luxury of the clergy, and in favour of that liberty which Rome had in ancient times enjoyed. Though banished in the year 1146, he returned again from Zurich, where he had taken refuge, and, under Pope Adrian IV. was condemned and executed in 1155. In the mean time the two great cities had strengthened themselves. Milan had in her alliance the cities of Tortona, Crema, Bergamo, Brescia, Placentia, and Parma. Pavia was at the head of Cremona and Novara. Verona, Padua, Vicenza, Treviso, and Mantua, who were nearly equal in power, maintained each its independence. Turin was at the head of the towns of Piedmont, and disputed the authority of the Counts of Savoy. The great feudatories were the Marquis of Montserrat and the Prince of Asti. To the south of the Po the city of Bologna had acquired great power, and exercised influence over Modena and Reggio on one side, and Ferrara, Ravenna, Faenza, Forli, and Rimini on the other. Florence had risen to superiority in Tuscany by the destruction of Fiesole, and had as allies the cities of Pistoja, Arrezzo, San Minato, Volterra, Lucca, Cortona, Perugia, and Sienna.

Such was the state of affairs in Italy when the diet of the empire of Germany, assembled at Frankfort in the year 1152, bestowed the crown of that kingdom on Frederick duke of Bavaria, of the house of Hohenstauffen, better known by the name of Barbarossa, the nephew of Conrad, his predecessor in that dignity. The new emperor is recorded by the authorities of his time to have been brave, just, and not addicted to cruelty, yet his reign inflicted the most severe visitations on Italy. The cities were zealous to defend the rights of self-government which they had obtained, and, though filled with factions, resolved to maintain them. They were surrounded with strong walls, impregnable against the arts of attack then practised; and they were well peopled with men, patient, brave, and abstemious, when a siege demanded the exercise of such qualities. The open country and the smaller towns, from which the numerous fortified cities drew their sustenance, suffered severely whenever an army traversed that country; and, to produce a greater pressure on the cities, the rude soldiery of that time not only destroyed the provisions they could not consume, but cut down the growing crops before they were fit to be harvested, or set them on fire, with the houses and the barns of the cultivators. Barbarossa viewed the whole of Italy as his subjects, and treated those who opposed him as rebels and traitors; and as the Ghibelines, who were the weaker party, adhered to him, his chief operations were directed against the Guelphs, of whom Milan was the main support and the centre of union.

Six times did the emperor cross the Alps with a numerous German army to reduce the country to obedience, and each time his attempts were frustrated. In 1154, in conjunction with the city of Pavia, he defeated the Milanese army, but could not take the city; yet he destroyed Tortona, and was then crowned, both in Pavia with the iron crown of Lombardy, and at Rome with the golden crown of the empire, though the ceremony was performed in the suburb, admission within the walls of the latter city being refused. After plundering Spoleto, sickness and desertion so thinned his ranks, that he led back the remnant of his troops, and repassed the Alps by way of Trent and the Tyrol. The most savage destruction was perpetrated in the retreat; but the cities were unassailed, and rejoiced in their freedom, though they did little injury to the retiring army. In the interval that followed, a civil war was carried on by the two parties, at the head of which were Milan and Pavia; but in this the latter, the weaker of the two confederates, suffered the most, whilst by the former the citizens of Tortona were received with sympathy, their houses rebuilt, and their fortifications restored.

Barbarossa entered Italy again in 1158, with the vassals who crowded to him from all parts of Germany. At Brescia, the terror of his name induced that city to renounce the alliance with Milan, which refused to receive the emperor. By the aid of the militia of Cremona and Pavia he was enabled to besiege Milan; but his engines being insufficient to beat down the walls, he resolved to starve it into surrender, and intercepted all provisions and destroyed the growing crops. In this situation of distress, Blandrate, an independent noble, known as a protector of Lombardy, with some others of the same rank, assumed the office of mediator, and obtained favourable terms. The city agreed to pay a tribute, and to restore the rights of the emperor, on condition that they should elect their consuls, and not be bound to open their gates to the emperor. Tortona and Crema were both included in this pacification, which was signed on the 7th of September 1158. A few weeks afterwards, a diet of the kingdom of Italy having been convoked at Roncaglia, fixed much wider bounds to the regal rights than the Milanese would admit, upon which they again took up arms and prepared to defend themselves. Another diet was called, which met at Bologna in the spring of 1159, and by whose decision Milan was declared to be under the ban of the empire. As that city was too strong to be captured, the first attempt of the emperor was directed against the allied city of Crema, which was compelled to surrender, after a siege of six months, in January 1160.

The German troops were exhausted by the severe duty of the siege, and their term of service having expired, many of them withdrew; but Frederick, with the Italian Ghibeline cities of Pavia, Cremona, and Novara, carried on the war by devastating the country of the Guelphs, and excluding all supplies from Milan. In June 1161, a new army reached the theatre of war in Italy, when the emperor resolved to reduce what he called his rebellious city. The defence of Milan was hopeless, but firmly maintained, when a fire, which destroyed the chief magazine of provisions, induced the inhabitants to surrender at discretion in March 1162. Frederick, though proud and severe, was not cruel, and never put to death by the hands of the executioner either enemies or rebels when vanquished. He ordered the militia of the Ghibeline cities to raze the walls, and so to destroy the buildings, that not one stone should be left on another. The poorer inhabitants were placed in villages at some distance from the place; and many sought hospitality in other cities, where their perseverance was recorded with applause, and where they spread the love of freedom and hatred of tyranny. The spirit of independence so rapidly increased that it was soon communicated to the Ghibeline cities; and the effect of it was to produce a confederacy of a most extended nature. Frederick had entered Italy in 1163, attended only by his splendid train of nobles, but without an army, under the impression that he could at pleasure call out the militia of the Ghibeline cities. He directed his steps towards Rome, where, on account of a contest for the papal chair, occasioned by the death of Adrian IV., he thought his presence necessary. Whilst in the south, a union was formed in the Veronese, which he deemed injurious to his prerogatives; and he hastened to call out the militia of the Ghibeline cities of Pavia, Cremona, Lodi, and Como, to lead them against Verona; but they were indisposed to the service, upon which he returned to Germany to collect an army, on whose exertions he might depend.

In October 1176 Frederick descended from the Grisons with his newly-collected army. His military operations were ineffectual; and whilst he advanced to Rome and to Ancona, the confederation of the cities of the Guelphs and the Ghibelines was cemented, and assumed the name of the League of Lombardy. Frederick had been repulsed at Ancona, whilst he had been victorious at Rome; but his victory proved useless. His army was attacked by disease, which swept away great numbers; and with the remnant he could scarcely protect himself from the increasing influence of the League, whose authority had already restored Milan, and built the new city of Alessandria, at the confluence of the rivers Tanaro and Bormida. In March 1168, the emperor, with but a very few troops, was enabled to effect his retreat from his Italian subjects, by the road of Mount Cenis, and soon prepared a new German force, which was to be employed in coercing them.

In the efforts to lead the Germans again into Italy, he was baffled by their reluctance, and remained, as far as regarded Italy, in a state of repose during five years. He sent, indeed, his warlike chancellor, Christian, archbishop of Mentz, to raise his party in Tuscany, the only district in which there existed any portion of attachment to the Ghibeline cause.

In October 1174, Frederick again entered Italy at the head of a powerful army, but was detained four months by the siege of the newly-built town of Alessandria; and the sickness among his troops, occasioned by the severity of the winter, so weakened him, that having abandoned the siege in April 1175, he was too weak to attack the forces of the League, and thus induced to enter on a negotiation. Much time was spent, but no plan of conciliation was adopted; and Frederick again sent into Germany for an army, which arrived in the spring of 1176 at Como, whither he was enabled secretly to join them; but he could get very little aid from the few cities of the Ghibeline party. He advanced to the neighbourhood of Milan, and at Lignano attacked the forces of the League. Though at first he met with success, yet the issue of the battle was so decisively against him, that his camp was pillaged, his army dispersed, and himself rendered a fugitive; but finally he escaped to Pavia, to contradict the report of his death, which had prevailed during several days. Negotiations followed this defeat. The pope and the Venetians acted as mediators, and in 1177 a truce for six years was concluded. During its continuance the political power of the League was strengthened and consolidated; whilst, on the other hand, the emperor had learned the lesson, untaught to his predecessors, of submitting to restrictions imposed by subjects on their sovereign. The truce was followed by the treaty of Constance in 1183, which secured the privileges of the cities, and recognised the prerogatives of the monarch, with certain necessary restrictions.

Barbarossa partook of the religious enthusiasm which infected all Europe, and, after the peace of Constance, repaired to the Holy Land, where, in 1190, he died of an apoplectic attack.

Though the peace of 1183 gave political freedom to the cities, yet this not being followed by any confederation, they each thought only of strengthening their defences, and of intriguing for power and supremacy. A party spirit was thus kindled, which spread and continued during the whole period that the emperors of Germany of the house of Hohenstauffen continued to exercise the shadow of sovereignty. The cities were soon divided again into Guelphs and Ghibelines, but had changed their party principles, the Ghibelines being the defenders of the papal power, and the Guelphs the assailants thereof. The party feeling within each of the cities was strong and active. In those where the Guelphs had the government, a large minority constantly opposed them; and the same was the case where the opposite faction had the upper hand. Noble and other families were engaged in long feuds with each other, which endured through generations, and were constantly occasioning open murders or private assassinations. The history of these cities is filled with narratives that exhibit human nature in forms most revolting to our best feelings.

A single, though far from a solitary, instance of the prevalent feudal proceedings, may not be without its use in showing the effects of such a state of society as existed in these cities. A noble Guelph, named Buondelmonte, of the upper vale of the Arno, had demanded the hand of a young lady of the Ghibeline house of Amidei; and his proposals having been accepted, preparations were made for the marriage. But a lady of another family, the Donati, stopped the lover as he passed her door; and bringing him into the apartment where her females were at work, raised the veil of her daughter, whose beauty was most captivating. "Here," said she, "is the wife I had reserved for thee. Like thee, she is a Guelph; whilst thou takest one from the enemies of thy church and race." Buondelmonte, dazzled and enamoured, instantly accepted the proffered hand. The Amidei considered this inconstancy as a deep affront; and all the noble families of Florence of the Ghibeline faction, about twenty-four in number, met, and agreed that he should atone with his life for this offence. Buondelmonte was attacked on the morning of Easter Sunday, as he passed the bridge on horseback, and was there killed. Forty-two families of the Guelphic faction then met, and swore to avenge the insult; and thus blood was shed to atone for blood. Every day some new murder or some open battle alarmed the citizens of Florence, during the space of thirty-three years. These two parties stood opposed to each other within the walls of the same city; and although sometimes in appearance reconciled, yet every little accident renewed their animosity, and they again had recourse to deadly warfare.

The nobility of Italy, who possessed extensive feudal estates in the intervals between the cities, and some in contact with them, were bound by their tenures to take part with the emperor in the hostilities he had carried on

History.

against the cities. By this they had been much impoverished and in debt; and their creditors were for the most part the inhabitants of the cities, to whom the estates were hypothecated. They were a high-spirited race, had by practice acquired great skill in arms, and were acuter and abler political intriguers than the magistrates of the cities. Some of the nobles, who had castles sufficiently strong, lands sufficiently extensive, and vassals sufficiently numerous, to defend themselves, became attached to the Ghibeline party. Those of them whose castles were weak from their situation, or near to cities too populous to be ruled by them, had been admitted to become citizens of such places, had assisted them in war, had obtained a considerable share in their government, and were for the most part compelled by their interest to become adherents of the Guelphic faction. The plains of Italy were thus deprived of all the independent nobility, who had become citizens of some of the free republics; but every chain of mountains was thickly set with castles, held by those who, whilst they maintained their own independence, professed to owe and to acknowledge allegiance to the emperors. As war was their sole occupation, they were often gladly received by the republics, which stood much in need of able captains. It seems that the independent nobles who became connected with the cities as commanders of the forces were not always, though most commonly, of the same faction; for the Ghibeline family of Visconti, which held most extensive fiefs, associated itself with the Guelphic republic of Milan. These nobles, however, when connected with the cities, soon acquired extensive influence, and became finally founders of families who obtained hereditary, and, some of them, sovereign power. Of these the house of Este, allied to the Guelphs of Saxony and of Bavaria, who had strong castles on the Euganian Hills, joined the republic of Ferrara. The family of Ezzel or Eccelino, whose fiefs and castles were at the foot of the Tyrolean range, and who were devoted to the Ghibeline party, formed connections with the republics of Verona and Vicenza. On the northern side of the Apennines, the fortresses of several Ghibeline nobles excited and maintained revolutions in Placencia, Parma, Reggio, and Modena; whilst on the southern side of those hills were the castles of other Ghibeline nobles, in turn citizens or enemies of the republics of Arezzo, Florence, Pistoja, and Lucca. In the lower valleys of the Po, as well as in the upper vale of the Arno, the castles of the Guelphic nobles supplied leaders to the republics in their vicinity.

The factious and ferocious state of society here briefly sketched continued during the whole of the reign of the family of Hohenstauffen; but it is only justice to observe, that in the latter years of that period the art of painting first made its appearance in Italy, and that the first dawn of the revival of literature became visible in the horizon, by the improvement made in the language, by the discovery of magnifying glasses and of the magnet, by the establishment of the university of Bologna, and by some writers of talent, to whom the literature and civilization of all Europe became deeply indebted.

During the nominal reign of the German family, no one of the individuals who succeeded to the title after the death of Barbarossa is deserving of notice, excepting his grandson, Frederick II., who attained the dignity before he had arrived at the age of eighteen. During his reign, Pope Innocent III. attained the pontifical chair; a man of rare talent, great learning, strict morals, and adequate energy. Though the founder of the mendicant orders of Franciscans and Dominicans, and of the fearful power of the inquisition, and though the instigator of the crusades against the Albigenses in France, all his acts originated in the view he took of the moral effect of the increase of the ecclesiastical power, and of its concentration in the head of the church. He made efforts in Rome to establish civil liberty, by forming a representative senate, to whom all power but the judicial was intrusted; but he issued his commands to all the princes of Europe in stronger tones than those of Gregory the Great, which, if obeyed, would have deprived them of all political liberty.

History.

Frederick carried on wars, in spite of the pope's anathema, with great success. In 1237 he defeated, at Cortenuovo, his opponents, who lost 10,000 men; and his subsequent activity gained all Upper Italy to his party, except the four cities of Milan, Brescia, Placentia, and Bologna. But Gregory IX., who had succeeded Innocent on the papal throne, induced the maritime republics of Venice and Genoa to rescue the Guelphs from destruction. This gave a turn to affairs, though Pisa still held fast to the emperor and the Ghibelines. A general council, summoned by the pope, pronounced his excommunication, and his party forsook him by degrees. The mendicant orders everywhere excited conspiracies against him; he became suspicious of every one around him, and was at length obliged to concede every thing to the pope; and, through the mediation of St Louis of France, he proposed, as the condition of his re-admission to the church, that he should go to the Holy Land and join the crusaders, engaging never to return. Whilst waiting the effect of his proposals at his castle of Florentino in Sicily, where he still ruled, he was seized with a dysentery, and died in December 1250.

After the death of Frederick, and the triumph of Pope Innocent IV., much confusion ensued, in which all freedom was extinguished. The pontiff was deceived in the expectation of general submission which he had formed. He was, during a progress, in some places received with coldness, and in others with disdain. The populace were in a state not to be restrained; the demagogues who directed could not rule them till they had assumed military and despotic power. In this progress the most unheard-of cruelties were perpetrated. In the single city of Padua there were eight prisons always full, notwithstanding the incessant toil of the executioner to empty them; and two of these prisons contained three hundred prisoners each. The Eccelinos became for a time absolute masters of the north of Italy, and were succeeded by the family of Romano, and they by Marten della Torre. The cities of Mantua and Ferrara fell into the power of D'Este, and Verona into that of Mastino della Scala. Palavicino became lord of Cremona, and in process of time, when the disorders had attained their greatest height, of Milan, Brescia, Alessandria, and Tortona. The whole of Italy, with the exception of Tuscany and the maritime cities, had learned that the rule of an individual was far better than that of a democracy, and quietly submitted themselves to a military commander.

During the period in which the emperors of Germany of the Suabian or Hohenstauffen race were the kings of Italy, the maritime cities of Venice, Genoa, and Pisa, had grown up to be powerful republican states, and were only by slight ties bound to the common sovereigns of Italy. The nobility who had been admitted to the rights of citizenship were the senators; and some member of their families was commonly chosen as a ruler, with the title of doge or duke. They were strict aristocracies, preserved in that form by laws which, whilst they gave security to their privileges, secured in like manner the rights and possessions of each individual. Under this state of security they naturally became wealthy, and their progress was accelerated by favourable circumstances. The Crusades, which animated the whole west of Europe, created a demand for shipping to convey troops and stores to and from the Holy Land; and thus a mercantile navy was called into being, which could at any time be easily A. D. 1260 to 1512.

converted into a military navy. It was in this way that Venice was enabled to take, and for a time to retain, the city of Constantinople itself. The commerce of the East had also greatly contributed to increase the wealth, and consequently the power, of these free cities. The chiefs of the Crusades, who returned from these expeditions, brought with them from Asia a taste for its luxuries; and for these the maritime cities became the storehouses, supplying the countries in the western part of Europe.

After the death of Pope Alexander IV. in 1261, his successor, Urban IV., among several princes who sought the government of Italy, selected Charles of Anjou, brother of St Louis of France, appointed him king of Naples, a senator of Rome, papal vicar of Tuscany, and finally king of Italy. This gave a new direction to the two parties, the Guelphs and the Ghibelines, which still distracted the country. One of them was considered as the friend, and the other as the enemy, of the French aspirant. Besides these parties, there were also the republics; and besides them, contests between the nobles and the people, in most of which the latter were, in the beginning at least, the conquerors. Charles invaded Naples, and defeated Manfred, the king, in 1265, and thus gave the superiority to the Guelphs, which he further increased by placing a garrison in Florence, and excluding from the councils the whole of the nobles, and all others of the Ghibeline party. He was for a short time alarmed by an invasion from Germany under Conrad, the grandson of the last Suabian emperor. This prince was only sixteen years of age when he arrived at Verona at the head of 10,000 cavalry, where he was joined by all the Ghibeline commanders who had distinguished themselves under his ancestor, and aided by the efforts of the Ghibeline cities, Pisa and Sienna. The citizens of Rome were so disposed to favour him, that on his advance they opened their gates and promised assistance. But all this zeal in his favour was of no avail. He passed the Abbruzzi Mountains, and at the foot of them fought a desperate battle in August 1268. It terminated in the total defeat of the Germans. Conrad, with the chiefs, were made prisoners, and, after a mock trial, were condemned and beheaded at Naples on the 26th of October 1268. After these executions, an uninterrupted exhibition of similar spectacles filled the two Sicilies, and some other parts of Italy, with such horror and dismay, that Charles of Anjou reigned triumphantly, and soon acquired the mastery over the republican cities.

Gregory X., who ascended the papal throne in 1272, saw the impolicy of his predecessors, who had given themselves a French master. He endeavoured to raise the Ghibeline party so as to counterbalance the Guelphs; and engaged Pisa, Venice, and Genoa, to co-operate with him in choosing a chief. The election was made the following year, when Rodolph of Habsburg, the founder of the house of Austria, was declared emperor. Martin IV., who was made pope in 1280, undid the work of his predecessor, and persecuted the Ghibelines with great fury. But in the mean time the popes had secured to the holy see the temporal power over the ecclesiastical territories. During this period hostilities took place between the maritime republics. The Genoese had assisted Michael Palæologus in his successful efforts to retake Constantinople from the Venetians, and had received for their reward the island of Chios. Near to Meloria, in a sea-fight, the Genoese had nearly annihilated the fleet of the Pisans; and in another battle, near Curzola, they had gained the command of the sea by their defeat of the Venetians.

Charles was preparing an armament in all the ports of Naples and of Sicily, with the intention of contending in Greece for the eastern empire. This induced him to levy taxes of great amount with excessive rigour, and the judges endeavoured to prevent resistance by striking terror into all those who declined or even delayed the required payments. John de Procida, the friend and confidant of Frederick and of the deposed Manfred, a native of Salerno, visited secretly the cities of both Sicilies, to re-animate the zeal of the Ghibelines, and to rouse their hatred towards Charles and the French. He had also obtained promises from Greece and from Spain. It was not necessary, however, to have recourse to foreign aid, for a sudden and popular explosion took place in Palermo. It was excited by a French soldier, who behaved rudely to a betrothed lady, as she was on her way with her affianced husband to a church to receive the nuptial benediction. The indignation of her family was on the instant communicated to the populace. The bells of the churches were ringing for vespers; the people answered by the cry, "To arms; death to the French." The French were furiously attacked in every quarter. Those who attempted to defend themselves were soon overpowered; others, who endeavoured to pass for Italians, were known by the pronunciation of the two words "*ceci*" and "*cieri*," which they were forced to utter, and on mis-pronunciation were instantly put to death. In a few hours more than four thousand persons thus perished in Palermo, and every other town in Sicily followed the bloody example. Thus the Sicilian vespers overthrew the dominion of Charles and of the Guelphs; separated that island from the kingdom of Naples; and transferred the crown of the former to Peter of Aragon, the son-in-law of Manfred, who was considered as the heir of the house of Hohenstauffen. The massacre occurred on the 30th of March 1282.

Florence had, by 1282, been led to a democratic state by the attainder of the nobles as a body, and, by its judicious regulations, had greatly strengthened the Guelphic party; but some disputes, which had originated in the neighbouring insignificant town of Pistoja, were extended to Florence, and in a short time divided the whole of Tuscany into two factions of Guelphs, called the *Bianchi* and the *Neri*, or the Whites and the Blacks, whose mutual animosity and hostility were continued till 1300, when, by the intrigues of Pope Boniface VII., and the instrumentality of Charles de Valois, the Bianchi were plundered and expelled the country, upon which a part of them joined the Ghibeline faction. In Lombardy the dying cause of freedom still continued to exist, and was at length rekindled; and the people, wearied out with the feuds of their nobles, between 1302 and 1306 drove them out. At this period, by the management of Philip le Bel, a Frenchman, Clement V. was chosen pope, and removed the seat of the papal throne to Avignon, where it continued till 1377. This gave room for the display of the spirit of freedom in Rome, and in all the territory of the church. The authority and almost the name of the emperor of Germany had been neglected in Italy during sixty years, whilst their minds were wholly occupied with internal disputes. At length, in 1308, the diet of Germany advanced Henry of Luxembourg to the imperial dignity, after three other princes had occupied that station. Henry VII. had little power to enforce obedience in Germany, and foresaw symptoms of opposition, which he wished to divert by flattering the vanity of conflicting parties, and uniting them in projects for extending his authority over the several parts of Italy. Henry crossed Mount Cenis, and appeared in Italy in 1310, accompanied by a few cavalry, not amounting to two thousand, composed chiefly of Belgians, Germans, and some Savoyards. At Turin he was waited on by many of the nobles of Lombardy and Piedmont, who at least professed obedience; and even the cities, in confusion and distress as they all were from their internal contentions, gave indications of a strong desire for tranquillity under their constitutional chiefs. Henry professed impartiality between all parties, and his conduct corresponded with his professions; but he

History.

wanted money, and it was issued out to him with great parsimony by all but the citizens of Pisa, who were extremely liberal, and increased his force with a guard of six hundred bowmen, who accompanied him to Rome, where he received the golden crown of the emperor from the pope's legate, without the walls, as the citizens refused admission to him and his troops, but had admitted a garrison of Neapolitans. The term for which his foreign troops had enlisted had expired on his coronation, and they mostly left his service; but the Ghibelines and Bianchi of central Italy gathered round him, and formed a respectable force. He made some ineffectual efforts to conquer the democracy of Florence, who had taken a garrison of mercenaries into their pay. He then, reinforced by the Pisans, marched towards Rome to contend with Robert, king of Sicily, who maintained an ill-disciplined force in that city, and expected reinforcements from the Guelphs of Tuscany. On the road, not far from Sienna, on St Bartholomew's day 1313, he received the communion from the hands of a dominican monk, and expired a few hours afterwards, with strong suspicions of having been poisoned.

When Henry died, disputes arose at the diet at Frankfort respecting his successor in the empire; but they seemed to have had little effect on the condition of Italy. In a few years most of the republican cities in the middle of Italy had fallen under the government of some distinguished military family, whilst Tuscany alone maintained a share of liberty, by selecting Robert, king of Naples, as its protector. The Ghibeline city of Pisa found a master in Uguccione della Faggiuola in 1314; and, after his expulsion in 1316, in Castruccio Castracani. Padua fell to the house of the Carraras. Alessandria, Tortona, and Cremona, became submissive under the Visconti of Milan. Mantua fell to the share of Gonza in 1328. In Ferrara the family of the Este established their hereditary power; and Ravenna became the patrimony of the Polentas, who had long held power there. In the other cities the same tyranny was established, but, from generation to generation, so uncertain in its administration as to increase the evils it created. These small princes adhered to Robert of Naples, whose greedy lust of power obtained the means of indulgence by Clement V. having appointed him vicar-general of Italy, designing thereby to hold the balance of parties in his own hands. Louis of Bavaria made his appearance in Italy in 1327, in order to put down both Anjou and the Guelphs. He was supported by the Ghibelines; but, by want of firmness, and a breach of his professions, so estranged them, whilst, on the other hand, the wickedness of Pope John XXII., who supported the Guelphs, had so cooled their zeal in his favour, that the two parties who had so long opposed each other, uniting in the cause of common freedom, were drawn much closer together.

At this period that estimable royal adventurer, John, king of Bohemia, the son of the Emperor Henry VII., made his appearance in Italy; and having been invited by the citizens of Brescia, and favoured by the pope, he was announced as the mediator and pacificator of the kingdom. He arrived in 1330. But his purposes were frustrated by the opposition of Tuscany, where a dread of the government of a single person was generally entertained. His fickle disposition made him soon abandon his objects, and he quitted Italy in 1333.

After his departure, Mastino della Scala, who had been one of his supporters, and who was lord of the half of Lombardy, and of the territory of Lucca, began to threaten the independence of Italy; but he was opposed by a league, headed by Florence, which led to hostilities; but they were soon terminated, and the freedom of Florence was thereby secured. The necessities of Mastino induced him to sell his city of Lucca to the Florentines, upon which the Pisans rose and took that city for themselves. After this transaction, the Florentines, disgusted with those who had caused the loss of Lucca, selected as their chief a military adventurer, who, in the Crusades, had obtained the title of the Duke of Athens; but, owing to his severity, they soon dismissed him. In Rome, torn by aristocratic factions, Cola Rienze was chosen tribune of the people, in order to restore the laws and tranquillity; but after seven months he was obliged to give way before the power of the nobles, in 1347. After a banishment of seven years, in 1354 Cardinal Albornoz was recalled; but his rule was short, having been killed in an insurrection instigated by the nobles. The Genoese, tired out with everlasting quarrels between the Guelphic families of Spinola and Doria, and the Ghibeline families of Grimaldi and Fiesche, drove them all out of their city, and elected their own first doge or duke. In Pisa the Ghibelines were divided into two violent parties, those of Bergolini and of Raspanti, when, after much contention, the latter succeeded in expelling the former, in 1348. At this period Italy suffered from a dreadful famine, which, in 1347, swept away, by absolute starvation, vast numbers of the inhabitants; and in the following year a pestilence of a most mortal nature spread over every part; and such was the suffering produced by these visitations, that it was calculated that two thirds of the whole population were destroyed by them. Another tremendous scourge followed, and was longer endured. After each peace, bands of dismissed soldiers were formed under chiefs, called *condottieri*, who carried on war on their own account, burning some towns, ransoming others, and plundering everywhere. They were mostly Germans, who had been called in by the Viscontis and Della Scalas. A Duke Werner, a Count Lado, and a Friar Morale, led bands of these robbers, who devastated Italy from Montserrat to the extremity of Naples, between 1348 and 1354. Meantime another war had broken out between the maritime republics of Genoa and Venice. The Venetians formed alliances with the Greek emperor and with Peter of Aragon. Formidable fleets were collected, one commanded by the Genoese admiral, Paganino Doria, and the other by the Venetian, Nicolo Pisani. A battle was fought between them on the 13th of February 1352, which proved indecisive; but in a second, fought in the following August, the Genoese were defeated with great loss. In two years success changed sides; and after a defeat of the Venetians in November 1354, a truce was agreed to, which terminated in a peace in the month of May following.

The family of Visconti had raised themselves to great power in the centre of Italy. John of that name had influence in Genoa, intrigued in Venice, and threatened to destroy the independence of Tuscany. He died in 1354; and his power and pretensions, being divided between his three nephews, became weaker, and received a check by the appearance of Charles IV., who again returned to Italy in 1355, where he was enabled to new-model the cities of Pisa and Sienna, and so far to overcome Tuscany, though but for a short period, as to compel even Florence to adopt the title of an imperial city. With but little real power he opposed the Visconti; but ended in obtaining money from them, as he did from most parts of Italy, in his progress through the country. In 1363, he liberated the city of Lucca from the dominion which the Pisans had obtained over it. About the same period Pope Innocent VI., by his legate, between 1365 and 1375, obtained absolute power over the cities of the papal dominions; but lost much of it again, from the discontent excited by the tyranny of the legate, and by the interference of Florence in favour of their freedom. Robert of Geneva, who was elected as pope, and took the name of Clement VII., established his court at Naples in 1378, under the protection of Queen Joan. He was opposed by another pope, namely, Urban VI. The church was thus divided between two popes and two colleges of cardinals, and the temporal power of the holy see was weakened. Several of the cities had been enfranchised by the Florentines; but those of Romagna, with some others, fell under the yoke of petty tyrants.

The continuance of the thirst for dominion of the Visconti in the centre of Italy, where they had rendered themselves masters of Genoa and Bologna, excited a general combination against them, at the head of which was Florence; and the old parties of Guelphs and Ghibelines were forgotten in this new and threatening crisis. In Florence the Guelphs were divided into two parties, the Ricci and the Albizzi. After great tumults, Michael de Lando, of low origin, but a brave and generous man, produced tranquillity in 1378. The party of the Ricci, which had thus been for a moment defeated, was essentially aristocratic, and numbered amongst it the members of the family of Medici, whose names are then for the first time to be met with in Italian history. This party soon afterwards, in another tumult, banished Lando, and those who had supported his nomination, and then constituted the former aristocracy more firmly than it had before existed.

In the other republics the same progress was made. The leaders of the democracy, or their heirs, created themselves tribunes of the people, and became a fresh aristocracy, with the power of transmitting it to their families. At Genoa, a civil war was carried on for a long time between the two strongest parties, but ended in their conferring the sovereignty, in 1396, on Charles VI., king of France.

In Lombardy, Gian Galeazzo, of a French family, had seated himself on the throne of Milan, and having rendered himself master of the smaller cities in that district, alarmed Sienna, Pisa, Bologna, and other considerable places. Being restrained, by the opposition offered by Florence, from attacking them at that time, he succeeded in a few years, and conquered most of them; and ultimately brought Tuscany itself into a dangerous position, from which it was relieved by a pestilence, which, amongst many thousands whom it swept away, carried off also the object of its dread, Gian Galeazzo, in 1402. This event gave a breathing-time to that part of Italy; and, during the minority of the son of Gian, many of the places he had taken were retaken. Milan fell into a state of anarchy, and the Venetians availed themselves of it to conquer Padua and Verona, whilst, on the other side, the Florentines captured Pisa; and Gian Maria, a youth, was only supported on the tottering throne of Milan by the arms of the hired mercenaries. His tyranny and cruelty is painted in the blackest colours by all the writers of his age; and he at length fell a victim to the indignation of some of the nobles, by whom he was assassinated, in May 1412.

In 1409, a new but transitory danger threatened the republic of Florence, by the invasion of Ladislau, king of Naples, which was no sooner repressed than the power of the Visconti became predominant. The Duke Philip Maria of that family, with the assistance of his celebrated general, Carmagnola, between 1414 and 1420, conquered all the states which had belonged to the family in Lombardy; and Genoa submitted to him in 1421. Venice and Florence then made a league in 1425, and General Carmagnola, having turned to these parties, conquered the whole of the territories on the river Adda, and secured them by the peace of Ferrara in 1428. The condottiero Braccio Montone contrived to make himself master of the city of Perugia, and of the whole of Umbria, and extended his power to Rome itself; whilst the Petrucci, in 1430, firmly established their power in Sienna.

After the weakening of Milan by the Florentines and Venetians, and owing to the constant disturbances raised in Naples by the party of Anjou against Alfonso of Aragon, there was no longer any dangerous preponderating power in Italy. There existed, however, constant hostility between the armed military bands, in two divisions, according to their usual practice. One of these was led by Braccio Montone, and the other by Sforza Attendolo. Francis Sforza was enabled to make himself, after the death of Visconti, master of the whole territory of Milan, in 1450. The Venetians, greedy of extended territory, made an alliance with some of the smaller states; Sforza made a counter-treaty with Florence, which, under the change of circumstances, providently changed its policy. At this period the house of Medici, by its wealth and its prudence, began to attract notice and to gain importance in Florence. The power of Milan, where Sforza ruled; of Venice, which possessed the half of Lombardy; of Florence, which was wisely directed by Lorenzo de' Medici; and of Naples, that was not in a state to venture on offensive war; formed, towards the end of the fifteenth century, the political balance of Italy, and, in spite of manifold feuds, gave confidence to each power that its independence was secure.

In 1494, Charles VIII., king of France, advanced towards Italy, designing to conquer Naples; and Ludovico Sforza came forward, first to support, but afterwards to oppose him, whilst the pope, Alexander VIII., in order to elevate his son Cæsar Borgia, courted the French alliance. The opposition to Charles was feeble, but the cruelties and the rapine which he caused or permitted filled Italy with disgust. Ludovico Sforza collected an army in the north, which induced Charles to leave one half of his forces to retain the possession of Naples, which he had gained. He was impeded in his retreat, and lost in it the greater part of his army before he could enter his own kingdom. That portion of his force which he had left in Naples was at length obliged to capitulate at Atilla in July 1496; so that, after two years of war of the most ravaging description, France did not gain the least footing. Louis XII., who had succeeded to Charles VIII. in April 1498, made pretensions to the government of Milan. He was opposed only by Ludovico Sforza, because Venice, who would have joined Ludovico, was engaged in an alarming war with the Turks; and Florence, from which the Medicis had been banished, was ruled by a seditious faction, intent upon subjecting Pisa to their authority. Pope Alexander, who had opposed Charles, formed an alliance with Louis, on condition that his relation Cæsar Borgia should be made Duke of Valentinois in France, and of Romagna in Italy. Frederick king of Naples, though aware that he must be ultimately the victim of France, was too much occupied in restoring tranquillity at home to take any active measures to protect Italy.

Louis, favoured by the position of affairs, passed the Alps with a powerful army in August 1499. He took some small towns by assault, and put the garrisons and most of the inhabitants to the sword; a ferocious proceeding, which produced universal terror, so that Sforza could make no opposition, but dispersed the army he had collected, and withdrew with his family and treasures into Germany. There he found protection with the Emperor Maximilian. The cities of the north of Italy opened with trembling anxiety their gates to the troops of the French king, and he was installed as Duke of Milan in that capital, whilst Genoa, which had been an ally of Sforza, made terms with France. After this hasty subjugation, Louis returned to Lyons. The insolence of the French, their violation of all national institutions, their contempt of Italian manners, the accumulation of taxes, and the irregularity of their administration, rendered the yoke insupportable. Ludovico soon became acquainted with the ferment which prevailed,

History.

and the eager wishes of his subjects to see him again at their head. He was on the Swiss frontier, and hastily collected a small force. With this he entered Lombardy in February 1500, having only five hundred horse and eight thousand infantry. Como, Milan, Parma, and Pavia, opened their gates to receive him; and after a short siege Novara capitulated. But Louis was active, and his general, Tremouille, advanced to suppress this rebellion with an army in which were ten thousand Swiss. Hired troops of the cantons were in both armies. When they met, these troops had parleys between themselves, and the part in Ludovico's army agreed with those in the army of Tremouille to murder their Italian fellow-soldiers, and to leave the service in which they had entered. This was executed. Ludovico Sforza was delivered up and sent to France, where he died after ten years' imprisonment; and the Swiss returned home with the wages of perfidy and the curses of Lombardy, whilst the French continued masters of the country till 1512.

The French then attempted to gain Naples, and a most infamous treaty was concluded with Ferdinand the Catholic, of Spain, who had engaged to defend that kingdom, by which that unfortunate country was subdued; and in the division of it quarrels broke out between the French and Spaniards, in consequence of which, after a battle had been gained by Gonzalvo, the general of the latter, the French were in 1503 completely driven out, and the kingdom of Naples became an appendage of the Spanish crown.

By the death of Pope Alexander VI., and the accession of Julius II., the pretensions of Cæsar Borgia vanished, as the new pontiff was more zealous to strengthen the holy see than to advance the son of his predecessor. With this view he formed a treaty with the kings of France and Spain, called the League of Cambray, in 1508, the object of which was to check the engrossing measures of the Venetian republic; but it having failed in that respect, by the cunning of the Venetians, his holiness, in 1509, entered into a treaty with the Venetians themselves, in which the king of Spain and the Swiss cantons were comprehended, the purpose of which was to drive the French out of Italy; but this project was abandoned by the pope, from the dread that the council of French and German prelates assembled at Pisa would be induced to declare his election to the popedom invalid, and dismiss him from the dignity. In the mean time Maximilian of Germany and the king of France had concocted an alliance at Blois, by which it was agreed to divide between them the whole of the dominions of Venice on the continent; and, in consequence of it, hostilities commenced in 1509. The cities surrendered to the French, the Germans, or the Spaniards, all of whom exercised the most abominable cruelties. The pope, in the midst of the conquests of the great powers, became alarmed, and, with the cunning of an Italian, attempted to free Italy from their ravages, by inflaming the emperor against the French, by forming a league with Venice, and by calling in the aid of the mercenary Swiss. The pope raised an army, commanded by the Duke of Urbino; and though it was defeated in 1511, he succeeded in forming a league, to which the prefix of Holy was given, on account of his being at the head of it, with the kings of Spain and of England, and which also comprehended the Swiss and the Venetians.

A powerful Spanish army from Naples, in 1512, advanced to assist the pope, commanded by Raymond de Cordova. He was gladly received by the people, but opposed by the most experienced of the French generals, Gaston de Foix, with whom he fought a most murderous battle near Ravenna, on the 11th of April 1512; and though the French were victorious, yet the loss of Gaston, who fell in the action, was more than a compensation for the defeat which the Spaniards had sustained. Maximilian suddenly betrayed his allies, recalled the German troops from the French service, and gave a passage through his territory to the Swiss to join the Venetian army. Ferdinand of Spain and Henry VIII. of England simultaneously attacked France, who was thus obliged to recall her troops from Italy, and abandon the country to the power of the Holy League. The liberties of Italy were then annihilated. Florence, with Tuscany, a country rich and factious, but not warlike, after being plundered by the Spaniards without pity or remorse, was delivered over to the banished but now restored Medicis, where Giovanni de' Medici, afterwards Pope Leo X., with some other members of that family, reimbursed themselves for their long proscription, by the abundant wealth they employed their power to extort.

History

Charles of Ghent, commonly called Charles V., already king of Spain, on the death of his grandfather Maximilian, was raised to the imperial throne in 1519. Charles, and Francis the king of France, had abundant subjects of contest; but Italy was doomed to become the theatre for their decision. Francis, in 1523, sent an army under Bonnivet to invade Lombardy and take possession of Milan. The city had time to collect stores and complete its defences, owing to the supineness of the French general, and thus was preserved from capture till the emperor could furnish an army of sufficient strength to meet Bonnivet in the field.

1512 to 1792.

In the next year the imperial army received such reinforcements that Bonnivet thought himself unable to resist it, and resolved to withdraw his troops. On the retreat he was wounded, and the command devolved on the Chevalier Bayard, who was killed in the battle; after which the remnant of the French escaped to their own country, leaving Lombardy in the power of the imperialists. Charles was so elated by the success of his arms in Italy that he resolved on invading the patrimonial dominions of Francis, and accordingly Pescara led his army into Provence, and began the siege of Marseilles; but the attempt proved unsuccessful, and its repulse encouraged Francis once more to make an attempt to retrieve the reverses he had suffered in Italy. The French passed the Alps by Mount Cenis, and the rapidity of their movements enabled them to enter Milan, which was unprepared for the attack; but the imperial general secured and garrisoned the citadel, which in some measure commanded it. Francis then laid siege to Pavia, which was strongly fortified, and garrisoned by six thousand veterans. The siege occupied several months, and thus gave time for Charles to collect his troops. Francis was resolved to fight, though urged by his generals to avoid a battle. On the 24th of February 1525, the two armies engaged; the contest was obstinate, and the issue long doubtful; but after dreadful carnage, the imperialists were victorious, Francis himself was taken prisoner, and with him Henry king of Navarre, and a few only of the body guard escaped. The French in Milan retired, and, in fourteen days after the battle, not a soldier of the nation remained in Italy.

After this last French attempt on Italy, which had, like all that preceded, only shown that a temporary ascendency could be obtained by that nation, but could never be retained, the preponderating influence was securely held by the Emperor Charles V. Most of the reigning houses disappeared, and their successors were appointed either avowedly or secretly by him. When the male line of the Marquis of Montserrat became extinct, Charles, in 1536, gave his dominions to Gonzaga of Mantua; and Maximilian II. in 1573, created it a dukedom. The Florentines made an attempt, after murdering the Duke Alexander in 1573, to regain their independence; but their efforts were unavailing, and Cosmo de' Medici was raised to supreme power by the influence of Charles. Parma and Placentia had been seized upon by Pope Julius II. for the holy see; but Paul III. in 1545 erected those states into a dukedom for his bastard Peter Aloes Farnese, whose son Octavio, in 1556, was invested by the emperor. Genoa, which, since 1499, had submitted to France, found a deliverer from that power in the person of Andreas Doria, who established a firm aristocracy, which overcame the conspiracy that Fiesco had projected to destroy it. Charles, in 1553, had conveyed Milan, and also the kingdom of Naples, to his son Charles. At the peace of Château-Cambresis, in 1559, Philip II., and Henry II. of France, renounced their pretensions to Piedmont, which was given to the legitimate heir, the brave Spanish general Emanuel Philip, duke of Savoy. In 1597, the legitimate line of the house of Este became extinct, upon which Cæsar d'Este, a natural son of the last prince, obtained Modena and Reggio by an enfeofment from the empire; and Ferrara was conveyed to him as a feudatory of the papal throne.

The end of the sixteenth century was a period of peace in Italy, and of such prosperity as could be expected after it had lost the foreign trade which had proved so lucrative, and which had been so long enjoyed by the discovery of the way to India by the Cape of Good Hope. In the next century only some insignificant changes of territory took place. Some reverses in Germany induced the Emperor Ferdinand II. in 1631, when the family of Gonzaga became extinct, to grant Mantua and Montserrat to Charles de Nevers, a protegé of France, whose descendants retained it till the war of the succession in Spain. In the peace of Chierasco in 1631, the cunning of Richelieu obtained Pignerol and Casale, which might serve as means of facilitating an irruption into Italy; but, in 1637, he was obliged to give up the latter fortress. The peace of Italy was not disturbed by any of the operations of Louis XIV. of France, and seems to have been durably secured by its neutrality being made one of the stipulations of the treaty of Turin in 1696.

The effects of the war of succession in Spain were extended to Italy. Austria conquered Milan and Montserrat, and the Duke of Mantua was expelled on account of his crimes. Montserrat was ceded to Savoy, and the two other cities retained by the house of Austria. The peace of Utrecht, in 1714, conferred Sardinia and Naples on the emperor, and Sicily on the house of Savoy; afterwards the two powers exchanged the islands, and the house of Savoy, thus gaining Sardinia, assumed the title of kings of that island.

The family of the Farnese became extinct in 1731, when the Infant Charles of Spain received the investiture of Parma and Placentia. In the war respecting the Polish succession, which broke out in 1733, Emanuel of Savoy, now king of Sardinia, formed an alliance with France and Spain. By this he was enabled to take possession of the duchy of Milan; but at the peace of Vienna, in 1738, he was compelled to restore it to Austria, being allowed to retain only Novara and Tortona. The Spanish infant, who had become king of the Two Sicilies, delivered up Parma and Placentia to the house of Austria. The family of the Medicis had enjoyed the title of Dukes of Tuscany with great tranquillity; but the last member of it dying in 1737, Francis Stephen, duke of Lorraine, by the preliminaries of the Vienna treaty, was invested with the sovereignty; and, in 1745, it was settled as the possession of the second son of the Lorraine-Austrian family. In the war of the Austrian succession, in 1745, the Spaniards conquered Milan, but were driven out by Charles Emanuel; for which service Maria Theresa conceded to him the districts of Vigevanasco and Bobbia, and some portions of Anghiera and of Pavia. Massa and Carrara fell by hereditary succession to the Duke of Modena in 1743. Parma and Placentia were taken possession of by the Spanish infant Don Philip, who soon lost it again; but, at the peace of Aix-la-Chapelle in 1748, he once more received it, and continued to hold it as an hereditary possession. Thus, at nearly the termination of the century, in 1792, the houses of Lorraine, Spain, and Savoy, were the rulers of all Italy except the states of the church, the duchy of Modena, and the republican cities, in which the decrepitude of old age was making rapid advances.

As the narrative of the events by which Italy fell under the dominion of Bonaparte is communicated in this work under the head FRANCE, it is only necessary to refer the reader to that article. When quiet possession of the peninsula had been gained in 1797, republicanism was in the ascendant at Paris, and the Cisalpine republic was formed. Lombardy was extended by adding to it a portion of the papal territory. Genoa formed another republic, called the Ligurian; and Venice, which had submitted without opposition, also adopted a republican form, though it was soon afterwards transferred to Austria by the treaty of Campo-Formio. Naples also was, in 1799, formed into a republic, under the denomination of the Parthenopæan. Amidst the greatest oppression and the most wanton cruelty, this state of affairs continued till their conqueror became first consul, when the Cisalpine republic was new-modelled after the pattern of France, and converted into the Italian republic, with Bonaparte as its president. In 1805, when the military regime was completed in France, and Bonaparte had become its emperor, the same kind of monarchy was forced upon Italy, and he was crowned at Milan on the 26th of May, with the iron crown of Lombardy. About the same time Naples was converted into a kingdom for his brother Joseph, who, however, was soon compelled to abandon it, in 1808, for the throne of Spain, and was succeeded by General Murat. For one of his sisters, who had married Paschal Bacciochi, Parma and Piombino were formed into a kingdom, to be called that of Etruria; but it was soon destroyed, and converted into a province of France. Though Naples was subdued, the legitimate monarch took refuge in Sicily, and was enabled to maintain himself by the assistance of the English navy and army. Whilst Murat reigned as king in Naples, and Eugene Beauharnois as viceroy in Milan, they were both summoned, with all the forces they could collect, to join the grand army for the subjugation of Russia. After the retreat from Moscow, both returned to their dominions with the remnant of their forces. Eugene maintained the fidelity for which he had engaged; but Murat, offended with Bonaparte, formed an alliance with the confederated monarchs of Europe. After the abdication of the imperial throne, Eugene withdrew, and the states in the north of Italy soon returned to the government of their ancient rulers.

On the return of Bonaparte from Elba in 1815, Murat took up arms, as he affirmed, for the independence of Italy. With the Neapolitan troops he advanced towards the north, and entered Bologna; but was soon driven from thence, and afterwards defeated near Tolentino, upon which there was an end of his kingdom. The capital was entered by the Austrian general Nugent, and Murat fled to France, whilst his wife and family found a refuge in Austria. Ferdinand returned from Sicily to the capital of his continental kingdom, and was received with delight by the inhabitants. Murat made a feeble attempt to recover his kingdom; but having collected a small body of troops in Corsica, and landed with them on the coast of Calabria, he was made prisoner, tried by a military tribunal, and shot. By the final treaty of Vienna, the following arrangements regarding Italy were agreed to, and still remain. The king of Sardinia received back all his dominions, according to the boundaries existing in 1792, with some few changes in the limits on the side towards Geneva. To these were added the city of Genoa, and the

History. territory attached to it in former times when it was a duchy. The emperor of Austria united with his hereditary monarchy the newly-erected kingdom of Venetian Lombardy, in which was included the districts of the Valteline, Bormio, and Chiavenna, parts of the Swiss canton of the Grisons. Istria was not included in the Austrian kingdom of Illyria. As the boundary between the popedom and Parma, the valley of the Po was fixed upon. The house of Este was again declared sovereign over Modena, Reggio, Mirandola, Massa, and Carrara. The Empress Maria Louisa received the state of Parma as a sovereignty for her life, after which it was to fall to the Duchess of Lucca and her heirs, who were to give up a territory in Bohemia to the Duke of Reichstadt, the son of Napoleon and Maria Louisa, who has since died. Prince Ferdinand of Austria received Tuscany, with the title of Grand Duke, as before his dismission, and the district of Piombino; and also the sovereignty of the isle of Elba, but reserving in that island the rights of Prince Buoncompagni Ludovisi. The Infanta Maria Louisa received Lucca as a sovereign dukedom, and with it a yearly pension of 500,000 francs, till the decease of the Empress Maria Louisa. The pope was fully reinstated in all his dominions, with the exception of a few small portions on the left bank of the Po; but Austria reserved the right of recruiting in Ferrara and Commachio. Ferdinand of Naples was again acknowledged as king of both Sicilies, and the republic of San Marino and the Prince of Monaco were guaranteed in the full enjoyment of their ancient rights.

The restoration of the old governments was not followed by the immediate return of tranquillity, and much less of contentment. A large army had suddenly changed its colours, and the officers serving in it feared that a change of masters might be unfavourable to their professional advancement. There was, or soon arose, a disposition to speculate on forms of government, to which Italy had always a strong tendency; and though it had been repressed by the military and inquisitorial power in the hands of Bonaparte, it was only stifled, and, when that power was destroyed, spread with great rapidity. This naturally engendered republican feelings; and the idea of uniting the whole of Italy into one large republic, to be administered solely by natives, was too flattering to the vanity of a people accustomed to view all foreigners as barbarians, not to meet with numerous adherents. The proselytes were chiefly found amongst those least capable of calculating the capability or the consequences of their projects. The spirit of change was deeply imbibed by the active part of the people, and especially those of immature age; the students in the colleges, the inferior officers in the civil and military departments, and the younger members of some of the noble families who were reduced to poverty by the exactions which had been practised by their late masters. In the recollection of what Italy had been fifteen centuries before, when she ruled the world, they overlooked many centuries during which she had since been subjected to Goths, Lombards, Germans, Normans, and Spaniards, and at intervals to the French. They never adverted to the condition of that most numerous class of all, the peasantry, who had formed the armies of Cæsar and of Pompey, when independent in mind and powerful in body, but had since become the most ignorant, thoughtless, superstitious, and degraded of all the serfs of Europe. Though there were abundance of revolutionary projectors, and extensive conspiracies formed, yet the hands that were to execute the purposes of such leaders completely failed when collected together, if opposed by only a mere handful of disciplined troops. This had been seen when Murat led a large army proclaiming the independence of Italy, and promising to deliver it from all its transalpine intruders. The same spectacle was exhibited in both the attempts at revolution which were made in Naples and in Piedmont. History

In Austrian Lombardy the same tendencies to revolution existed as in the other parts of the peninsula; but they were checked by the vigilance of the police, and by an armed force, which, as they spoke a different language from the conspirators, was not to be infected by the general mania of the natives. In the other parts of Italy, where the army was composed of natives, the prevalence of revolutionary views was easily communicated, and perhaps nowhere prevailed more generally than amongst all ranks of the officers. This was especially the case in Naples, where the army that had been created by Murat, and officered by him, was placed by the restored king under the command of the Austrian general Nugent, to the great mortification of all in the service. The French military regime was exchanged for that of Austria; the taxes upon land were increased; and, by an agreement with the pope, many of the abolished monasteries were re-established. These arrangements gave force to the speculative opinions which prevailed of a republican kind, and originated many secret societies, the most extensive of which was that of the *Carbonari*, which, if we may trust to the oaths and declaration as published by their enemies, was of the most atrociously murderous and diabolical kind.

Although the societies of the Carbonari had been opposed by another society, called the *Calderari*, adhering to the royal party, and employed by the police, it was said that they counted amongst their members, and those who favoured their proceedings, more than six hundred thousand individuals, including all the provinces of the kingdom. This vast combination, though to a certain degree known to exist, and to be numerous, made no public demonstrations of its force till a revolution had broken out in Spain. The excitation produced by that event spread throughout Italy, but the strongest effect was experienced at Naples. On the 2d of July 1820, Michael Morelli, a lieutenant of cavalry, and Luis Minichini, a priest, excited some troops quartered at Nola, by some violent harangues, to cry aloud, "God, the King, and the Constitution." They were soon joined by an officer of the guards with about twenty men, and the next day marched to Avellino, the capital of the province, where one of the conspirators had already declared the insurrection, and gained over more troops, when the united bodies advanced to Montefort, and took up a position, which they surrounded with intrenchments. Some troops were sent by the government, under General Campana, to reduce them to submission; but these troops discovered no disposition to act. Another general, Carascosa, with more soldiers, was pushed on; but they also refused to fight their brothers. On the 5th, General Pepe, at the head of a regiment of dragoons, proceeded from Naples and joined the insurgents, and was then declared their chief. Messengers were sent from the army to the king with petitions, requesting him to grant a constitution. He had no troops that could be relied on, and promised to present them with the plan of a constitution in eight days, and in the mean time dismissed his ministers, and replaced them by some of the leaders of the troops. This did not satisfy the impatient insurgents, and they demanded that within twenty-four hours the Spanish constitution should be adopted. The king appointed his son viceroy, and he assented to the proposition in his father's name.

The Spanish constitution thus proclaimed, was that of the Cortes of 1812 in Cadiz, of which no one in Naples had any knowledge, nor could even a copy of it be found in the city at the time of its adoption, as a fundamental law of the regenerated kingdom. In ten days, without a drop of blood being shed, a military revolt placed the revolutionists in the possession of the full power of the kingdom. An insurrection almost immediately broke out in Sicily, which, acting on the same principles, required independence; and the populace having broken loose, committed many disorders, such as breaking open the prisons, robbing the rich, murdering several persons of rank, and amongst these Prince Catholico, and assassinating others; so that on the 17th of July, three days after the events in Naples were known, fifteen hundred persons were killed and wounded in the city of Palermo, and confusion prevailed in every other part of the island. General Pepe was sent with a body of troops to restore tranquillity. He found the cities in a state of horrid confusion, some taking the part of the Neapolitans, and others insisting on independence. This state of misery continued till the whole insurrection in Naples was quelled.

Whilst Sicily was thus suffering the worst of horrors, the revolution in the continental part of the kingdom proceeded with less confusion. An assembly was convened, and adopted the Spanish constitution with some few trifling alterations. Though suggestions were made by some of the members, that some conditions taken from the English or French constitutions, or from some of those states in Germany which had recently received constitutions, would be desirable, they were scarcely attended to, and none of them acquiesced in. A great military force was decreed, to consist of fifty-two thousand regular troops, two hundred and nineteen thousand moveable national guards, and four hundred thousand local national guards, besides ten thousand gens-d'armes and coast-guards. The spirit of the regular troops could not be relied on, as many of the best of the officers had resigned their commissions. In a very short time the treasury was exhausted, though it had been left in a prosperous state; and it became necessary to borrow money from a Parisian banker, who advanced 1,500,000 ducats at a high rate of interest. The expenditure had increased at the rate of 4,084,000 ducats, whilst the income had diminished at the rate of 2,916,000 ducats, annually.

In these new hands every branch of the administration had become confounded, and embarrassed each other; the courts of justice decided nothing, the number of criminals increased, and trade was stagnant. These circumstances existed at Naples when the congress at Troppau, consisting of the emperors of Russia and Austria, and the king of Prussia, with their ministers, and the ambassadors from the other powers of Europe, had assembled, and in November had decided on a military interference in the affairs of Naples. Austria at this time had marched an army of eighty thousand men into her Italian provinces, under the command of General Frimont. Great Britain and France had each placed a naval squadron in the Bay of Naples, which were appointed to watch over the safety of the king and the royal family. These preparations excited the feelings of the several parties in the capital, producing on one hand suspicion and distrust, and on the other hope and joy. The king of France had offered to mediate between the parties, and suggested that the king should have the veto, the choice of his ministers, and the power of dissolving the assembly; but such propositions received no attention.

The three combined monarchs had on the 20th of November written a letter to Ferdinand, inviting him to meet them at Laybach; and the king of France had urged him to take this step. He resolved on doing so, and announced his resolution to the parliament on the 9th of December, and required that, during his absence, no changes in the constitution should be made. This communication produced much violent debate, and the answer given was a resolution, "that any proposition to alter the Spanish constitution being contrary to the oaths of the king and the parliament, they consent to his majesty undertaking the journey, on the condition that he will take the proper means to secure the acknowledgment of that constitution." To this resolution the royal reply was, that his majesty had never entertained any designs to change the constitution; but that, to avoid a war, it was advisable, by the king's mediation at Laybach, to obtain the sanction of the congress to what had been done, and that no further changes should be made during his absence. The parliament persisted in their resolution, and the king, on the 10th of December, declared that his mediation should have no other object than to maintain in its integrity that Spanish constitution that had been already sworn to, and to avert a war. The crown prince was then appointed regent; the king and his consort embarked in an English ship of the line on the 13th of December, landed at Leghorn on the 19th, and thence proceeded through Florence to Laybach.

The prince regent seems to have given way to the impetuosity of the parliament, to have passed some very revolutionary laws against the nobles of Sicily, and prepared as well as they could to arrange an army, which then was composed of fifty-four thousand troops of the line, and sixty thousand militia and volunteers; and they all appeared very energetic in the cause they had espoused.

When the king arrived at Laybach he was soon made acquainted with the decision of the congress, not to acknowledge as legal any transactions which had passed in Naples since the 5th July; and that the power of suppressing what was deemed a military revolt should be intrusted to the emperor of Austria. This resolution was made known by the king to his son, who acted as regent in Naples. At the same time the ambassadors of the combined powers made known, through the secretary of state for foreign affairs, to the prince regent, that an Austrian army was ready to enter the kingdom and to occupy it; and that if that was insufficient, a Russian army would also receive orders to join their force. The regent replied that he should make this known to the people, from whom he should not separate himself, because in all that had occurred great moderation had been shown, and the greatest respect displayed towards the royal family. The regent replied to the king, that as he could not believe the communication from his majesty to be a voluntary act, he should adhere in every way to the people, and share all dangers with them; upon which the ambassadors of the allied powers withdrew from Naples.

Preparations were now made for defence, and a proposal, that for the present the constitution should be suspended, and the regent declared dictator, was negatived. General William Pepe called to arms the whole of the people, arranged under ancient names, such as the legion of Brutus, of the Samnites, and others, and added them to the regulars, thus mustering a hundred and fifty thousand men, but many badly armed and clothed, and worse disciplined. The plans for defence were well arranged had the troops been well composed. The Austrians advanced, the first encounter happened on the 5th of March, and by the 10th a general dispersion of the whole army had taken place. It is not necessary to relate the several movements of the two armies. Many of the Neapolitans were killed in their flight; but the Austrians assert that they lost in all the combats not more than seventy men. The Neapolitan troops of the line soon joined themselves to the Austrian army, and the volunteers and militia returned to their homes. The Carbonari talked loudly of carrying on a guerilla war amongst the mountains, but it produced no effect. Naples, with the fortresses of Gaeta and Pescara, capitulated on the 23d of March; the lodges of the Carbonari were dissolved, the leaders, including the two generals, Pepe and Carascosa, obtained passports to foreign countries; and the last sparks of the revolution were speedily extinguished.

History.

The king had arrived at Florence, whence he arranged a provisional government, which speedily abolished the whole of the republican institutions, and restored such as had previously existed. The troops of the line were disarmed and disbanded, and the volunteers stripped of their arms and accoutrements. The police was established on its ancient footing; and some of the leaders of the revolt were prosecuted, of whom a few were executed after trials before the restored tribunals. A detachment of the Austrian army passed over to Sicily, and in a short time restored tranquillity in that island, after having disarmed a few parties of guerillas that infested the mountainous parts of it, whilst those who had commanded them fled into Spain. The restored government conducted the prosecutions with great mildness. Forty-three of the most conspicuous persons were brought to trial, of whom thirty were condemned to death, but only two of them, Morelli and Gilvati, were executed. On the 22d of September an amnesty was issued, from which only eleven persons were excepted, viz. General Pepe, the monk Minichini, Concilio, Carascosa, Rossarol, and six others, all of whom had taken refuge in England. Thus, in little more than fifteen months, the Carbonari insurrection was completely defeated, and the people returned to their usual habits, occupations, and gratifications.

The revolution which broke out in Piedmont whilst that in Naples was in operation, originated in the same causes, but varied in its progress, because it was more especially of a military character, and headed by persons of more weight, as well in the civil as in the military departments. The chief leaders of the insurrection were the Marquis Carlo de St Marzano, son of the minister for foreign affairs, Colonel Provano de Collegno of the artillery, the Counts St Michael and Santa Rosa, officers of the staff, Captain Count de Lissio, and some others, forming a confederacy to which they had given the name of the Italian League. They had resolved to select as their chief Prince Carignan, the heir apparent, who, they asserted, felt great zeal since the revolution at Naples, and was the best qualified to become the prince or king of New Italy. According to their representation, he had, on the 6th of March, acted with them, on the 7th he had declined proceeding, and on the 8th he had again consented to the revolution. On the 10th of March the revolt began in the regiments at Fossano, Tortona, and Alessandria, where the officers had gained over the men by spreading rumours that the Austrians had resolved to disband the Sardinian army, and to garrison the fortresses with their own troops. In vain the king contradicted the rumour; the insurrection increased, and a council of the officers, of which Ansalti was president, issued a declaration in the name of the Kingdom of Italy. From Alessandria the infection spread to Turin, where the general cry was "Long live the king and the Spanish constitution." The people in the capital remained quiet, and a part of the garrison was marched against the insurgents.

On the 12th of March the king issued a proclamation commanding tranquillity and obedience, affirming that the garrisons of foreign troops should never be admitted; but on the same day the officers, with some of the students, seized on the citadel of Turin, by which the populace became excited, and in crowds exclaimed for the Spanish constitution and for war with the Austrians. Upon this the king, who had assented to the resolutions of the congress of Laybach, could not yield to the popular cry, and resolved to abdicate the throne; and on the 13th he did so, appointing, in the absence of his brother Felix, who was the next in succession, but at Modena, Prince Albert Carignan as regent. The whole of the ministers were then dismissed, the state prisoners liberated, and the Carbonari were everywhere triumphant, except at Nice, to which city the king had removed. The new regent found himself compelled to obey those whom he had expected to lead, and declared for the Spanish constitution, but with a reserve in behalf of the king's consenting to it. He then appointed new ministers, a council or junta, and promised to convene a parliament.

History.

In Novara and some other places a dislike of the Spanish constitution was displayed; and in the whole of Savoy an aversion to the revolution prevailed. Amongst those who had favoured the revolution great differences arose. Many, and those the most thoughtful, preferred the constitution of France with two legislative bodies, to that of Spain with a single one. On the other hand, the revolution found many partisans in Lombardy; and many of the young men from Milan and Pavia hastened to join the revolted troops at Alessandria, which was the central point. Prince Felix at Modena refused the crown, declared the abdication to have been forced, and consequently illegal, and placed Count Galieri della Torre as commander in Novara, to take the command of the loyal troops and suppress the rebellion. This event tended greatly to damp the spirits of the revolutionary party; they still, however, remained triumphant in Turin, where the ambassador from Austria was dismissed, and preparations made to assemble a force and invade Lombardy under the command of Count Santa Rosa. But on the night of the 23d of March, on which the resolution had been taken by the council, the prince regent fled to Novara, thence to the Austrian headquarters, and then to Modena; but, being refused admittance to Prince Felix, he took up a short residence at Florence, and afterwards served in the French army which restored royalty in Spain in 1823.

. The revolutionists continued to encourage their party by assurances of speedy assistance from France, and of great accessions by the revolting of the Austrian troops; but the news of the defeat and dispersion of the Neapolitan insurgents among the Abbruzzi Mountains, which arrived at this period, inclined the Piedmontese to attempt a treaty, by which an amnesty should be granted, and stipulations made against the entry of any foreign troops. This, however, proved ineffectual, for the troops at Novara, under Della Torre, outnumbered any the insurgents could collect; and in Turin many abhorred the new system, and it was their desire that, without foreign troops, the revolt should be suppressed; but Felix at Modena had applied to the Austrian commander, and Count Bubna at the head of five thousand men joined forces with Della Torre, at two o'clock in the morning of the 8th of April at Novara. The troops of the insurgents appeared before that city at daybreak, and a battle ensued. They fought bravely, but were at length defeated. The native troops advanced to Turin, and the insurgent fortresses surrendered to the Austrians. The junta at Turin dissolved itself, and on the 10th the citadel was delivered up to Della Torre. The king renewed his abdication, and his brother Felix assumed the title of king. His power was now as unrestricted as that of his brother had been, and he instituted a tribunal for the investigation of crimes, and punishing the offenders; but most of them had escaped, many by way of Genoa to Spain, and others through Switzerland to France. It was shown before the tribunal that many of those who were arrested had acted by orders from Prince Carignan at the time he was the legal regent of the kingdom, and upon this ground they were unanimously acquitted. The property of sixty-five persons who had escaped was declared to be in a state of sequestration. Twenty-one others were declared guilty of high treason and condemned to death; and the same number were doomed to the gallies, with the confiscation of their goods. Of all these, only thirteen were apprehended, amongst whom were two who had been condemned to death. Only one, however, was executed;

he was a captain of cavalry, named Garelli. The other, in his flight by sea, had been driven on shore and captured; and showing that he did not return by design, he was only banished for life.

This mild administration of the judicial tribunal, with a general amnesty, and rigid decrees to prevent any secret societies being formed, soon restored tranquillity; and the absence of so many leaders of revolution seems to have extirpated the roots of that spirit which, for a short period, had threatened a most fearful civil war. As the revolt in Spain in the year 1821 had been one of the exciting causes of the insurrections in Naples and Piedmont, so it appeared that the revolution in France which seated Philip of Orleans on the throne of that kingdom was the proximate causes of the disturbances which broke out in Italy in 1831.

The complaints in Italy were general, and the remedy sought varied according to the opinions in the several states; but there was one opinion in which all who were dissatisfied united, namely, that the only cure for the evils they complained of was to be found in a general government, which should unite under one legislative body, composed wholly of Italians, the interests of all the states into which the country is at present divided. The feeling towards the ultramontane barbarians, for such they had been taught to consider the rest of the European nations, was by far the strongest and the most universally diffused, and an appeal to that feeling was a certain way to form combinations with the avowed object of expelling them.

If some secret societies had existed in Italy before, they increased in number and became more apparent after the transactions in Paris; and the most eager hopes were held out by those who took the lead in such societies, that if they came to an open rupture with their sovereigns, they might rely on effectual assistance from the newly-established power in France.

The combinations formed, though watched by the police, continued to increase till they were thought by their leaders to be sufficiently powerful to act with effect. The first disturbance began at Modena, on the 3d of February 1831. It was led by one Minotti, and consisted chiefly of young men. The troops were called out, and some fighting in the streets took place, in which the insurgents had the worst, and retreated to Minotti's house, where they were shut up; and cannon being brought, they surrendered with their leader, and were made prisoners. Thus all appeared again tranquil; but two days afterwards intelligence arrived from Bologna that the insurgents in that city had been successful, and that its influence extended to Reggio. A new and much more formidable revolt then broke out. It gained strength, so that the Duke of Modena deemed it wise to withdraw from his capital, escorted by his troops, and accompanied by his prisoners, Minotti and his companions, and to take refuge in Mantua, where was a strong garrison of Austrian troops. He left at his departure a council of regency, which the people soon dissolved, and then nominated a provisional government, upon which the populace plundered the palace, destroyed the custom-houses on the frontiers, and committed other disorders.

At Bologna, a city of sixty thousand inhabitants, there was only a small garrison of papal troops, not exceeding six hundred in number. On the 4th of February an insurrection took place, chiefly composed of young men, many of them the students of the university. They assembled round the palace of the cardinal legate, who was absent, and required of the pro-legate the resignation of his authority, and that it should be delivered over to a provisional government. He at first refused, then hesitated, and at length complied. The soldiers received and obeyed orders from the newly-appointed council; but their commander, with the pro-legate, withdrew to Florence. The temporal power of the pope was abolished by a decree of the provisional government, and a national guard on the French model was ordered to be formed. This success at Bologna spread the spirit of revolt through all the delegations from that city to Ancona; and the latter city capitulated, with its citadel, to a slight force of the insurgents which appeared before it. A great part of the papal territory was thus under the insurrectionary power. Their force indeed entered the Apennines, intending to advance to the city of Rome itself; but being disappointed in the expectations they had formed of some revolutionary movements in that city, they abstained from any attempt on it.

In Parma the transactions nearly resembled those in Modena. The duchess was compelled to withdraw, and, escorted by her troops, found an asylum at Piacenza, when her subjects also formed a provisional government.

Strong expectations had been indulged by the insurgents of similar movements in the other parts of Italy, and especially in Piedmont and Tuscany; but no symptoms of it were manifested in them, and the whole of Lombardy under the Austrian power remained in a state of anxious tranquillity. Austria had drawn a large force from her hereditary dominions, which had reached the Italian provinces, and was said to amount to a hundred thousand men, well disciplined and well appointed. Had the revolutionary bodies, who began to assume some regular order, been in possession of even common prudence, they would have avoided any step which could have provoked or justified Austria in interfering in their affairs, which, knowing the tendency of the Austrian court, they might have been convinced, would be pleased with a pretext for undertaking active operations.

Instead of temporising or disguising their views, no sooner was the provisional government assembled, than, vain of their newly-acquired power, they issued a proclamation inviting the Lombards to join them in their federation. "Brave patriots of Lombardy," said they, "follow the example of France, imitate the example of Italy, burst asunder the chains with which the holy alliance hath fettered you. You are the slaves of foreigners, who enrich themselves by despoiling you, and by rendering you daily more miserable. On the day of your rising, forty thousand of our patriots will march to assist you in crushing the Austrians. Let there be no delay, for there is danger in hesitation. Display your courage, fellow-countrymen, and despotism will flee from our lands." Similar addresses were issued to the subjects of the king of Naples and of the king of Sardinia; but they had suffered too much by the transactions of the year 1821 to be easily excited; and besides, those who might have proved the most active leaders had been banished, and were dispersed in various countries. Under the mild and paternal government of the Duke of Tuscany, whatever dispositions might exist, or whatever sympathy might be felt for the neighbouring insurgents, no manifestations were displayed, but tranquillity was universally enjoyed.

France, at the period when Philip was hardly seated on the throne, had declared that she would not permit Austria to interfere in Italy; but at a subsequent period, when the new monarch had become firmly fixed in power, an explanation was given, stating, that the declaration did not bind him to take any measures to prevent such interference. The Italians who had revolted were, however, buoyed up with the expectation of assistance from France, and the provisional governments spread the delusion long after it was known that the expectation was vain.

France was not at that time in a condition to take any effectual part. Her army was not formed, nor her financial credit established, till after the fate of Italy was decided. She could only come in contact with the insurgents by forcing a passage through Switzerland; and, having suc-

History.

ceeded in that, she would have to encounter the well-appointed armies of the emperor of Austria or of the king of Sardinia, or of both united. The negotiation between Austria and France seems to have terminated in an understanding that the former power might make use of its troops to suppress the several insurrectionary parties in Italy, but not permanently to occupy the several countries in which they prevailed.

The troops of Austria did not suspend their operations on account of the negotiations with France. The Po was passed immediately after the promulgation of the address inviting the Lombards to insurrection. One division of the army advanced to Modena without opposition. The duke returned to his capital, and was reinstated in his power. His conduct towards the insurgents was mild; some of them were brought to trial, and a few convicted, but Minotti was the only one who suffered death. Another division marched to Parma; the inhabitants submitted; the duchess returned to her palace, and granted a free pardon to all persons connected with the revolt, excepting those who had occupied seats in the civic congress; and they suffered no infliction except that of being declared incapable of filling any office in the public service during the next three years.

In Bologna, to which the Austrians advanced, some efforts were made for the defence of that place, the seat of the provisional government; but they were so inadequate that the army entered without any opposition, and speedily all the other cities and towns surrendered except Ancona, where the members of the temporary government had fled for refuge. In their flight they had taken Cardinal Benvenuto, and carried him with them as a hostage or a prisoner. As the Austrians advanced towards Ancona, and no prospect of escape for the revolutionary leaders presented itself, the leaders of the insurgents pressed the cardinal to enter into a treaty, by which an indemnity should be given to all political offenders on condition of surrendering the city and the citadel. He at first refused to enter into any negotiation; but at length, under a protest that he had no power to do so, he signed a treaty to the effect proposed, and the city immediately submitted to its former sovereign. The same submission must have been made in twenty-four hours to the Austrians, and the pope refused to ratify the cardinal's stipulations.

Legal proceedings were then instituted against all such of the insurgents as had signed the act of the provisional government which had declared the abolition of the temporal power of the pope, broken their oaths of military obedience, or published irreligious or seditious writings. Several were tried and condemned to different degrees of punishment, but not a single life was sacrificed. It was said that this mitigation of punishment was adopted at the suggestion of the French ambassador at the court of Rome. That minister could not, however, feel much satisfaction at an apologetical paper put forth by the provisional government immediately before its dissolution at Ancona. In that manifesto they stated, "that a principle proclaimed by a great nation, which had solemnly promised not to permit its violation by any European power, and the declaration of guarantee given by a minister of that nation, had induced them to give their assistance to the movements of the people in the several provinces."

Within six weeks from their commencement, all the disturbances in Italy were quieted, and the Austrian troops had been withdrawn to their own territory. In the papal dominions, however, there was much confusion, owing principally to the undefined limits of the power of different constituted authorities. These had caused partial revolts, and the miserable papal troops were incapable of suppressing them. His holiness applied to Austria for some troops, which entered his dominions, and enforced submission. This movement had been notified to the French ambassador, whose answer left no apprehension on the part of that power; and therefore great surprise was excited when, about a month after, a French fleet, with an army on board, appeared before Ancona, and by a fraudulent attempt succeeded in seizing upon that city with its citadel, driving out the pope's troops, and exercising many excesses towards the inhabitants. This transaction occurred in February 1831. It led to some detailed negotiations, which at last were settled by a treaty on the 16th of April. By it the French were to remain in Ancona, but no reinforcements were to be sent to them. The general who had made the capture was to be recalled. The troops were not to go beyond the walls of the city, they were to be maintained wholly at the expense of France, they were to interfere in no internal affairs, and were to depart as soon as the pope should have no longer occasion for the assistance of any Austrian forces. In this equivocal situation, the French troops at present occupy one of the best ports in the Adriatic Sea. It is not the business of a work of this kind to enter into speculations on the motives which for the last four years have influenced the king of the French in his conduct regarding Italy.

Having thus sketched, with as much detail as the limits of this work will allow, the history of Italy from the time when the dissolution of the Roman empire took place to the present period, we must remark, that in compressing the events of fourteen centuries into a few sheets, it has been scarcely possible to do more than produce a chronicle rather than a complete history, and therefore the dates of the greater events only have been given, so as to be useful for the purpose of reference. The causes which led to these events, the characters of the great actors in them, and the effects produced by them, would have opened a wide field, which might have been explored with delight, but which would have encroached too much on the subjects required to be treated in this work.

We have, however, here pointed out the origin of the several states which now compose the land of Italy, and at what time and by what means they had attained their rank as sovereignties. The actual condition of these sovereignties will be found in their alphabetical order in this work; but the notices of the preceding pages on the history of Italy will be found sufficient to enable us to dispense with the minute historical details of each of the states that now exist.

Physical Condition.

We now proceed, therefore, to take a view of Italy as a whole, and to describe those physical circumstances common to it in that view.

Italy is bounded on the north-east by the Austrian provinces of Illyria and Tyrol, on the north-west by the cantons of Switzerland, and on the west, in a small part, by the kingdom of France. The southern part, however, which in shape resembles a boot, is surrounded by the sea, having on the north-east the Adriatic, on the south-east the Ionian Sea, and on the south and west the Mediterranean. Its sea-coasts are for the most part protected by lofty acclivities. On the north-east shore, however, an estuary is created by the mouths of the river Po, which form a kind of delta of swampy and marshy land, whose insalubrious atmosphere acts as a powerful protection against any maritime attacks.

The extent and population of the several states which compose the whole of Italy is shown by the following table, which includes the great islands of Sardinia and Sicily, and the smaller islands on the coast, but does not comprehend Corsica, which, though inhabited by an Italian race, forms at present a portion of the kingdom of France.

Name of the State.	Extent in Square Miles.	Population.	Capital Cities.
Kingdom of Naples	43,052	7,434,300	Naples.
Kingdom of Sardinia	29,534	4,123,000	Turin.
Austrian Lombardy	18,450	4,278,902	Milan.
Territory of the Church	17,572	2,592,329	Rome.
Grand Duchy of Tuscany	8,759	1,275,000	Florence.
Duchy of Parma	2,253	437,400	Parma.
Duchy of Modena	2,145	379,000	Modena.
Duchy of Lucca	434	145,000	Lucca.
Republic of San Marino	44	8,400	San Marino.
	122,243	20,673,331	

Thus Italy may be considered about the extent of Great Britain and Ireland, but as containing nearly three millions fewer inhabitants.

The face of the country is much diversified by lofty mountains. The most stupendous mass of these elevations, which forms the northern boundary, has been most fully described in this work in its proper place, under the article ALPS. The second range of mountains, the Apennines, runs nearly through the whole of Italy. These commence in the maritime Alps with Mount Appio, between Tende and Coni, at the southern point of Piedmont, in latitude 44. 12. north, where the pass of the Bochetta is formed. At first they take a direction to the north-east, and then trend to the south-east, and at length to the south-west, when they are lost in the Mediterranean Sea at Cape Passaro in Sicily, in latitude 36. 35. In Upper Italy the Apennines run along near the shore, and the foot of them is washed by the waves of the sea in the territory of Lucca, where they form the Gulf of Genoa. In Tuscany also they nearly touch the coast till they enter the papal dominions, when they run along the centre of the peninsula, and encompass the Abbruzzis and Molise, and pass through Basilicata and the two Calabrias, to the most southern part of Continental Italy. They pass under the straits to Sicily, where they spread over the eastern coast of that island, and are joined with the gigantic Mount Ætna, after which they vanish under the sea. The Apennines are covered with woods quite to their summits. Amongst the trees chestnuts especially abound, and the fruit of them is used by the natives as a most valuable substitute for corn during a great part of the year.

The Apennines in no case attain the elevation of the Alps, and have only a few very lofty rocky points, the highest of which are Gran Sasso, near Aquila, in the province of Abbruzzo, which is 8255 feet above the level of the sea; and Velino, which is 7870 feet. In winter the range is covered with snow, and it is somewhat late, especially on the northern sides, before it melts. The mountains thus furnish to the inhabitants an abundant supply of that indispensable luxury in a warm climate, ice.

A great uniformity is observable in the composition of these mountains, which consists chiefly of calcareous stones, though in the extreme north and south parts there are many variations, but in the centre there are no rocks of primary formation. They in many parts abound in tuffa; but the main range exhibits no specimens of volcanic matter, which are only to be seen on the south-eastern coast of Italy; Vesuvius, the extinct volcanoes of Nemi and of Albano, and the lava stream of Borghetto, not belonging to the Apennine range.

In their long progress through the greater portion of Italy these mountains send forth some remarkable shoots or spurs. To those on the west belong the Montagnolo and Montagnata, in the neighbourhood of Siena; the mountain Lora, near to Rome; and the rocky chain of Sorrento, which extends to Capri, in the Terra di Lavoro. On the east are the inferior ranges of the march of Ancona and of the district of Urbino, and especially the branch which projects between Acerenza and Venosa, and proceeds to Leccese, where it is lost in the sea, under which it probably proceeds, till it emerges from the water, and then continues to proceed through the Grecian ranges of Corfu and Arnauth.

Besides the Apennines, there are other mountains, which, though not far removed from them, yet manifestly do not belong to, and have no apparent connection with them. The most remarkable of these are the mountains of Sorriano and of Fogliano, near Viterbo; Sante Oreste, near Civita Castellana; Monte Cavo, between Frascati and Velletri; and the Volture in Puglia; all on the western side of the main range. Besides these, are the volcanoes, either active or now extinct, viz. Vesuvius. Capo de Monte, San Elmo, Camaldoli, Pausilippo, Solfatara, and Monte Nuovo. The most remarkable capes or promontories which surround the shores of the peninsula are, Martini delle Melle, Manara, and Mesco, on the coast of Genoa; Piombino and San Stefano, on the shore of Tuscany; Linara, Anzo, and Circello, in the territory of the church; Licosa, Palinuro, Felta, Surero, Zambrone, Vaticano, Armi, Sarta, Spartevento, Stilo, Nizzuto, Colonne, Saracino, Roseto, Volta, San Vito, Turco, Assinella, and Acquabella, on the shores of Naples. To these may be added the following in the island of Sicily, which are of great importance to all the navigators of the Mediterranean Sea, viz. Peloro, San Croce, Passaro, Scaramis, Granitula, Fero Voco, St Vito, Dell' Ursa, Gallo, Zassarano, Orlando, Carara, and Melazzo.

The northern division of Italy is copiously supplied with streams of water from those capacious reservoirs formed at the foot of the mountain ranges of the Alps. Those lakes are composed of water, partly arising from springs, but chiefly from the melted snow and ice of the lofty summits around them. These lakes are never frozen in the winter, but run in continual streams, and thus serve the constant purpose of irrigation as well as of internal navigation, till they disappear in the rivers which proceed to the sea.

The largest of these lakes, called Lago di Maggiore, or Lago di Lucarno, begins in the Swiss canton of Ticino, but soon enters Italy, and then, between the dominions of Sardinia and Austria, extends to Sesto. It is nearly fifty miles in length, and varies in breadth from five to eight miles. It is shallower than most of the other lakes, being in the middle not more than twenty-five feet deep. It is 750 feet above the level of the sea, and is fed by the river Ticino and twenty-six brooks. It contains in it the celebrated Borromean Islands, for a description of which see this work (vol. v. p. 16). Its water issues forth by the river, which retains the same name as at its entrance till it joins the Po. The Lago di Lugano is partly also in the Swiss territory, and is of less considerable extent, but of great depth. It is about twenty-four miles in length, and from two and a half to six in breadth. Its surface is 870 feet above the level of the Mediterranean Sea. It receives the water of forty-three brooks or rivulets, and discharges it partly by the river Tresa into Lago Maggiore, and partly by means of an artificial canal into the small lake of Piano, a little to the eastward.

The lake of Como, celebrated for the romantic beauty of its borders, is wholly in Italy. It is about thirty-five miles in length, and in no part exceeds three miles in breadth, but it is of very great depth. It is formed by the river Adda and 195 smaller streams. It issues forth by the river, which bears the same name as at its entrance, but with an increased volume of water, and serves to fructify a great extent of land. At Bellagio it divides into two branches, one of which terminates at the city of its own name, and the other at Lecco. Lago d'Iseo is about twenty miles long and six broad; it is chiefly supplied by the streams of the Oglio, which issues from it again and runs to the Po. Lago d'Idro is small, being only seven miles in length, and through it the river Chiese passes before it joins the Oglio. Lago di Garda is the most extensive of all the lakes of Italy, covering a space of 315 square miles, or 201,600 English acres. It receives the water of the Sarta, and its only issue is at Peschiera, into the Mincio. It is of sufficient depth to carry vessels of the greatest draft of water. These vast reservoirs are of unspeakable advantage, both to the internal connection of one part of the country with the other, and to the several occupations of agriculture. As the slope of the land is regular and gentle from these lakes to the river Po, nature has thereby formed the means of distributing, with comparatively little cost of labour, the water over an extensive portion of the land, and in that due proportion which the nature of the soil or the description of the crop may require. In many parts streams of water are made to pass rapidly over the fields that require it, and what is not absorbed by the earth is received again into canals, and, at lower elevations, again passed in a similar manner over other fields, till the surplus fluid at length reaches the river Po.

As these modes of disposing water to the greatest advantage are almost peculiar to Upper Italy, and by their extension have been productive of the most beneficial effects on the fruitfulness of the soil, as well as on the internal communication, a sketch of their commencement and early progress can scarcely be destitute of interest.

After the decline of the power of the German emperors of the Saxon race, who had succeeded to Charlemagne, several free states were formed, of which Milan became one of the most flourishing; but war having been kindled amongst these states, most of the others combined with the Emperor Frederick I. against Milan, and, in 1162, captured and almost destroyed the city, laying waste the fields; but, during the continuance of hostilities, a change of fortune favourable to Milan, and the gaining of a battle, led to a peace in 1176. The energy and industry which this free state had displayed in war became equally manifest in peace. The canal then, as now, called Naviglio Grande, was begun to be constructed in 1178, or rather perhaps restored, for it is probable that the citizens of Pavia, eighty years before, had dug the canal, which had been partly filled up and rendered altogether useless during the continuance of hostilities.

The canal was at first only carried to Abbiategrasso, but the benefit was found to be so great, that, in the year 1220, the canal of Muzza was added to it. In 1269 the canal of Vettabbia was extended and lengthened. It had been originally constructed in 1037, but, as is stated by Giuleni (*Storia di Milano*, vol. iv.), was long neglected. In 1350 the canal of Treviglio, or Fosso Bergamasco, was begun; and, in 1460, the Duke Francesco Sforza first planned that of Artesana. These, though in some degree designed for the purposes of navigation, were chiefly planned and regulated to administer to irrigation. Navigation was only permitted two days in the week, and the other five days the water was used to enrich the land. It seems very probable that advantage to the soil from irrigation was known prior to any of the dates here stated as the commencement of these canals. That some progress was made as early as the year 1138, appears from a contract made in that year by the monks of Chiaravalle and Vicoboldone, in which are the following conditions: "*Ut monasterium possit ex Vectabia trahere lectum* (a canal) *ubi ipsum monasterium voluerit, et si fuerit opus liceat facere eidem monasterio fossata super terram ipsius Johannis* (the vender), *ab una parte viæ et ab alia, &c. possit firmare et habere clausum* (sluice) *in prata ipsius Johannis.*" A similar contract of the following year, and several of subsequent dates, are still in existence. The whole water of the Vettabbia belonged to those monks, having been granted to them by a charter of the Emperor Frederick II.; and the fame of their skill in the management of water was so great, that the chief of Milan, Napoleone della Torre, intrusted to their care the construction of works for draining the environs of that city, whilst Rinaldo, archbishop of Cologene, employed them in improving the marshes in his dominions. These ecclesiastics confined their attention and labours exclusively to irrigation, and did nothing for navigation; but they were the first to introduce the practice, since become so extensive, of selling their water by the hour, the day, or the week, and are said to have gained to their convent 60,000 partiche, or about 10,000 acres, of the best meadow-land in Italy.

Progress in the conducting of water must have been made in Italy centuries before the subject had attracted attention in the other parts of Europe. The learned Frisi, in his work (*Nuova Raccolta d'autori che trattono del moto della aqua*), speaking of the canal of Muzza already noticed, says that it was planned with the most perfect skill, and formed a masterpiece of art. The canal of Martesana is still seen with surprise. It receives its water from the Vaprio and the Adda; is carried between stone walls five Italian miles, on a level twenty-five feet above the bed of the Adda, parallel to it, in order to preserve the level; and distributes its water to the fields, which it could not otherwise reach without great labour and expense.

The subsequent progress of the management of water, and its beneficial application to agriculture, belongs more properly to the description of Lombardy, where it will, under that head, be found, than to the more general subject of Italy; but the early state of that art belongs to the history of the first dawn of a useful practice in the peninsula taken as a whole.

The north of Italy, as may be gathered from the description of the lakes, abounds in rivers. The principal of these is the Po, which conveys to the sea the water of most of the other streams. It originates in Mount Piso, in the Alps, and takes an eastern direction through the great valley of Lombardy, till it enters the Adriatic. The whole length of its course is about 330 miles, but for the first eighty miles it is scarcely more than a brook. The rich plain that is watered by it and by its tributary streams is 330 miles in length and 170 in breadth, and consists of the greatest extent of highly fertile land that exists in Europe. The course of the stream is very rapid, the water running at the rate of more than four miles an hour. A vast quantity of mud and other substances is brought down by this great force of the water to the lower part of the river, and being there deposited, tends to raise the bottom; and though the effect is in some degree mitigated by throwing up the substances on the banks, and thereby forming strong dykes or embankments, the bottom of the river has in many parts become higher than the land on both sides of it.

Though much labour and expense are applied to preserve the embankments, yet, when the snow and ice on the Alps melt suddenly, great inundations are experienced. The chief tributary streams which contribute to form the mass of water of the Po fall into it on the left bank. These are the Agogna in the dominions of Sardinia; the Ticino, the boundary between Sardinia and Austria; and the Adda, the Oglio, and the Mincio, in Austrian Lombardy. The water which increases the Po by its right banks are the streams of the Tanaro, the Trebbia, the Oreglio, the Arda, the Taro, the Parma, the Ena, and the Secchia. The next considerable river of northern Italy is the Adige or Etsch, which comes out of the Tyrol, passes Trent and Verona, and enters the Adriatic a little to the north of the mouths of the Po. It does not in summer discharge much water, and is only navigable a short distance higher than Verona.

Central Italy does not abound in rivers, and most of them are of short courses. The most considerable is the Arno, which rises in the Apennines, at the foot of Mount Falterone, runs through Tuscany, and enters the sea near Pisa. It is navigable for small craft, but the chief interest it excites arises from the rich and beautiful valley which is watered by it in its passage to the sea. The rivers which rise in the Apennines and run to the eastward, are for the most part mountain streams or torrents, occasionally dry, and, except when the ice and snow melt, contributing but in a small degree to augment the waters of the Adriatic.

The south of Italy contains few rivers deserving the notice they have received. The Tiber, in the papal state, descends from the Apennines, not far from the source of the Arno, and continues a course of nearly 150 miles, in which it passes Rome, and enters the sea about fifteen below that city. It is turbid, rapid, and deep; but at Rome does not exceed a hundred yards in breadth, and is only navigable from the sea to that city. The only other river in that territory is the Pescara, which runs into the Adriatic.

The Neapolitan dominions, though abounding in brooks and rivulets, which are valuable to the agriculturist, and with mountain streams, sometimes swelled into torrents, and at other times nearly destitute of water, has few streams of any length. The most important of them is the Ofanto, running eastward to the Gulf of Manfredonia, the Basiento, the Salandretto, the Agri, and some others; all of which empty themselves into the Gulf of Taranto. Those which run to the westward are the Garigliano, emptying itself into the Bay of Gaeta, the Volurno, and the Silaro. None of these are navigable, and their mouths are for the most part surrounded with swamps, which generate malaria, and are highly injurious to human life.

In a country extending from north to south through ten degrees of latitude, there must be a great difference of climate from the position alone; but besides that, the climate of Italy is influenced by the proximity of lofty mountains in some of its divisions, and by the influence of the air from the sea, which almost surrounds the other parts. If we follow the classification of Saussure, we may divide the climate of Italy into four regions. The first extends from latitude 46. 28. to 43. 30., and thus comprehends the whole of the Austrian and Sardinian dominions, and the other territories to the north of the Apennines, with the legations of Bologna, Ferrara, and Romagna. In this region the quicksilver in Reaumur's thermometer descends to 10 degrees below zero; the lagunes at the mouths of the rivers are frozen; and sometimes in January and February the snow remains from ten to fourteen days on the ground. Delicate plants do not grow except in sheltered situations; but the mulberry trees flourish, and rice is grown. The slight night-frosts appear in November, and some years as late as April. Even in summer a benumbing cold is brought down from the Alps, by a violent storm of northerly wind. The second region extends from 43. 30. to 41. 30. comprehending Tuscany, Lucca, the papal states, the Abbruzzis, and the whole of the western shore to the south of the Apennines, though some part of the latter does extend as far north as 44., but, from being sheltered by the mountains, has a climate similar to the southern part. This is the appropriate climate for the growth of the orange, the lemon, and the olive; but, even in this region, the snow is occasionally to be seen on the fields. The third region extends from 41. 30. to 39., and comprehends the greater part of the continental dominions of the kingdom of Naples. Here snow is rarely seen, and never remains; and the quicksilver seldom falls below three degrees, and all plants of the agrumenous tribe flourish in the open air. The fourth region extends from 39. to 35. 50., and comprehends the southern part of Calabria, and the island of Sicily. The quicksilver rarely falls below zero, and snow and ice are unknown except on the summits of the mountains of Ætna and Sila. The tropical fruits come to perfection in the open air, the sugar-cane flourishes, the cotton plant ripens, the date trees are seen in the gardens, and the enclosures of the fields are formed by aloes. It will be obvious that this classification cannot be universally applied, and principally attaches to the flat land of Italy. Thus the positions on the sides of high mountains, the vicinity of the sea, and the volcanic nature of the soil, all have an influence which must cause many local variations in any classifications, and form exceptions to what is generally correct. The tops of the Alps in Savoy and Piedmont are covered with perpetual snow. The Apennines are commonly clothed with it from the middle of October till the beginning of April; and on the highest mountains of Abbruzzo, the Majella and the Velino, it remains from September till May. The northern part of Italy, including Tuscany and the papal states, does not generally present that charming aspect which people from the north picture to themselves of the garden of Europe; and they are only introduced into that region on proceeding to the east from Manfredonia, or to the west from Terracina. There the winter is scarcely colder than our September; vegetation proceeds without interruption; and the air is filled with the most aromatic odours.

The climate of Italy, represented, as it frequently is, in the most glowing colours, is not without great and serious annoyances and inconveniences. There prevails from May to September a burning heat; the sun, with its perpendicular rays, threatens to destroy every vegetable; this burning atmosphere produces a brown landscape, unrefreshed by a drop of rain; when the air of the cooling sea breezes is scarcely perceptible, or is so changed as to bring with it from the shores of Africa only a thick, damp steam, whilst a subterranean heat glows perpetually under the volcanic soil, and periodically sends forth noxious vapours injurious to the health of men and of beasts, and which have tended to produce depopulation in many extensive districts. To these evils may be added the annoyance produced by numerous swarms of insects, which fill the air, visit the dwellings, and are a constant source of vexation. The vast lagunes at the mouths of the great river, the Pontine Marshes, with similar swamps on the sea-coast, and in many other parts, tend to generate miasmata, that shorten human life, and are among the causes that the proportion of deaths to the whole number of inhabitants is greater in Italy than in any other division of Europe.

The inhabitants of Italy are a mixture of races, compos-

Religion and Learning.

ed of Gauls, Germans, and Arabians, who at various but distant periods have immigrated into the peninsula, and mingled with the few aborigines, whose language they have expelled; and from it has been framed a speech, which by cultivation has attained a peculiar character, and become, notwithstanding its variety of dialects, a common bond of union. The language used by the best writers is nearly the same in every part of Italy; but that of the lower classes is so very different in the several divisions of the country, that those born in one can scarcely understand the conversation of the natives of the other. All the educated classes can comprehend and enjoy the writings of Dante, Petrarch, Boccacio, Tasso, and Ariosto composed in the Tuscan dialect.

In Italy the inhabitants universally adhere to the Roman Catholic church; or, if any differ from it, the number must be very inconsiderable, as there are no public celebrations of any other religious rites but such as are prescribed by that communion, except that the Jews in Venetian Lombardy, in Leghorn, in Rome, and in Ancona, have permission, but under some rigid restrictions, to establish synagogues. The foreign Protestants also may celebrate their rites in their own language, under the sanction of the ambassador or consul of their nation. The established clergy are very numerous, and said to amount to 500,000 persons, or one in forty of the whole population. The number of sees, which formerly exceeded that of the bishoprics in the rest of Christendom, has been greatly reduced, as well as the greater part of the monasteries, which once deluged the cities and large towns. The churches, however, still possess great riches, and are everywhere sumptuous in their decorations and ornaments, containing much of what is most magnificent and glorious in art, or most refined in taste, elegance, and beauty. The exterior of the churches is very imposing, and the ceremonies are performed with the greatest degree of pomp and solemnity.

The higher clergy possess great power, and all of them enjoy immunity for their persons and goods, and in most cases are freed from taxation. The secular priests are under the superintendence of the bishops, and the monasteries under the chiefs of their several orders. Though the extent of the influence and power of the church, and its universality, are the same as in Spain and in Portugal, its exciting cause and its associations are very different. In those countries the religion is a species of chivalry, originating in the idea of the conquests achieved over the Moorish Mahommedans, and combined with all the traditions on that subject; but in Italy it is chiefly to be traced to the progress made in the fine arts. It is associated with painting and statuary, with music and with architecture, and, as in Spain, has little connection with the moral feelings of integrity, chastity, temperance, industry, and the domestic relations. These virtues, where they exist, owe but little to the institutions of the church, of which they are unshaken though but feeble adherents. Confession and absolution are the substitutes for those virtues, and little beyond the value of those substitutes is inculcated in religious instruction.

In no part of Europe is the education of the humbler classes so neglected as in Italy, taken as a whole; for though some advances have recently been made in Lombardy and in Tuscany, and will probably continue, yet nothing is thought of or projected in the other territories, on the subject. The instruction of the poor is wholly in the hands of the ecclesiastics, and nothing can be worse conducted. It is a wonder to find a countryman that can read, and a handicraft workman in the towns that can write his own name is equally singular. The institutions for the higher kinds of education are also far behind those in the other countries of Europe. Amongst these are the colleges and lyceums, where the instruction is partial, and neither calculated to impress with taste, nor to excite freedom and extension of thought. The studies are directed to logic and some classics; but the sciences are neglected, as are the languages of other countries, their customs, their intelligence, and their modes of thinking and reasoning. Mathematics are scarcely known, but casuistry is sedulously inculcated. The *Collegia Ambrosiana* and the *Collegia Brera* in Milan form exceptions to the description here given, but in everything but classical literature they are far from being well conducted.

The universities where education is completed are sufficiently numerous, and mostly of ancient date in their foundation. They are, Salerno, founded in the year 1100; Bologna, in 1119; Naples, in 1224; Padua, in 1228; Rome, in 1248; Perugia, in 1307; Pisa, in 1329; Siena, in 1330; Pavia, in 1361; Turin, in 1400; Parma, in 1422; Florence, in 1443; Catania, in 1445; Cagliari, in 1764; and Genoa, renewed and extended in 1783; to which may be added that of Modena, which, after long neglect, has recently been re-established.

The dates of these institutions may serve to show the probable course of study originally introduced, when the works of the schoolmen and the casuists entirely engrossed the public mind. Some few improvements may have been ingrafted on these foundations, but they have been of little efficacy in exciting to study, or in forming a considerable proportion of enlightened scholars.

In almost every one of the cities of Italy there have been long-established literary and scientific societies, which have cherished and encouraged learning among their respective members. These were begun in the fifteenth century, and have multiplied and increased ever since. They have contributed, since the restoration of learning, to its preservation, and have been in a great degree the means of bringing the talents and industry of the scholars into public notice. They are too numerous to be even named here. One of the earliest, as well as the most celebrated, is the *Academia della Crusca* of Florence, which still exists, and had for its object the perfecting of the language, by which great renown has been gained. The most flourishing of these societies in the present day are the Imperial Institution of Milan, and the Academy of Sciences at Turin. The institutions for the promotion of the fine arts are numerous; they are in connection with schools, in which painting, sculpture, and architecture, are taught by competent masters. The most useful of these are at Florence, at Rome, and at Bologna.

Italy abounds in collections of books, and especially of manuscripts of great antiquity, and of high value. The libraries in general are, however, very deficient in works of modern literature and of science. The most distinguished of the libraries are that of the Vatican in Rome, the Ambrosian at Milan, that of St Mark in Venice, and those of the Magliabechi and the Medici at Florence. There are in every part of Italy museums of great value, and most of them are arranged in the most perfect manner. All of them are with the greatest liberality thrown open to the public, and are thereby made the common property of all nations. Each palace of the men of eminent rank, and each public building, is a cabinet of art; and each city boasts of its antiques or of its modern works of art. The most distinguished of the museums are those of Florence and of Naples. Picture galleries are to be found everywhere, and present to the inspector of them many of the finest specimens of that delightful art. The churches, too, are most abundantly graced, as well by their architecture as by the exquisite pieces which exhibit the skill of the painters or the sculptors. The greatest loss that Italy had to lament was the removal of the best works of art by the French invaders; but, fortunate-

National Character.

ly for the country, the events of 1814 and 1815 led to their being again restored to the several places which had been robbed of them. There are botanic gardens attached to most of the universities, and several in the vicinity of the larger cities; and there are astronomical observatories in Bologna, in Padua, in Milan, in Florence, and in Palermo.

The clergy have already been noticed; and in viewing the inhabitants of Italy generally, it is proper to advert to the class next to that body in rank, but superior to them in number. The nobility consists of a vast number of families, each member of which continues through all their generations to retain their titles, even though they may be destitute of wealth. In most of the dominions they have little or no influence as a body on the measures of the governments. In the papal states, in Sicily, in Sardinia, some patrician power exists, and some feudal rights are exercised, and in Genoa a shadow of their ancient dignity is retained; but in the other parts not even a shadow of power is to be found amongst them. They have the barren titles of prince, duke, viscount, marquis, or count. Many of them possess extensive landed estates, which are for the most part majorats, or strictly entailed on the eldest son, and many of these are said to be at present deeply mortgaged. As no provision is thus made for the junior members of such families, they commonly enter the church or the army, and sometimes, though rarely, obtain offices in the civil service of the government. Of late some of the nobility have directed their attention to agriculture; but none of them, except in Venice and in Genoa, have applied themselves to commerce. From the condition of this class, it is usual to find amongst them the whole of the family residing in the palace of the head of it, with their wives and children, if they have any. As money rent is not commonly paid for the estates, but the produce of these divided between the proprietors and their occupiers, the necessaries for the support of such families reach them directly; and, except for purposes of show or of luxury, very little money is necessary. Although some members of the noble families have devoted themselves to the promotion of literature, of science, or of the fine arts, yet the great body live in the silent enjoyment of their rank and property, or, when mixing in society, do so in those crowded but economical assemblies, where they can, with little interruption from plebeian intruders, enjoy the patrician feeling of their dignity. In such families, the foreigners that may be introduced to them do not receive, or in general expect to receive, any hospitable attentions; nor indeed is hospitality one of those good qualities by which Italians are distinguished in any of the ranks of life.

It is generally reported that the morals of this class have been gradually improving of late years, and that the practice of each married lady having her favourite lover or cicisbeo, after the birth of her first child, is rapidly disappearing. In regard also to gambling, it is said to have been practised to a less ruinous extent of late years than in former periods. One of the greatest, or at least most usual, gratifications of the people of this rank, is a box at the opera, where they most commonly attend in the evening, and where, enclosed by curtains, they can receive the visits of their friends, without interrupting the pleasures they derive from the representation and the music.

The burghers in the cities have now none of the power which they enjoyed in the many cities which were once denominated free. The municipal power is concentrated in the hands of the several governments; and, where corporations do still exist, they have no other right than that of presenting humble representations or suggestions on inferior and local subjects. The more affluent inhabitants of the cities, comprehending those of the legal profession, the bankers, the merchants, and the superior artists, amongst whom may be included the possessors of the smallest landed estates, are not numerous; but they mix more with strangers than the nobles, and have fewer national prejudices. They appear to know that all born beyond the Alps are not necessarily barbarians or semi-barbarians, and amongst them foreigners may find the best associates.

The lower class of the town population are in bad repute, both as to morals and instruction. They are represented as more acute than honest, and are reported to be only capable of being restrained from violations of life and property by the activity of a very vigilant police.

Whatever may be the faults of the Italian nation, one good quality is obvious; their ready assistance to suffering humanity. All the cities are filled with charitable institutions, wherein infants, the helpless aged, the diseased, and the destitute, find refuge and relief; but it must be acknowledged, that no country has more need of such institutions, for in none are there to be found so great a number of beggars, nor so numerous a body as, in all the cities, take little care for any thing beyond the passing day or even hour.

The greater part of the population of Italy is, however, to be seen in the country, devoted to the pursuits of agriculture. A few, a very few of them, are in circumstances of moderate affluence; a few more may be represented as in a state of comparative ease, enjoying a bare sufficiency to support life; but the great body, to whom all others bear a slight proportion, are in the most wretched condition. They are the occupiers of small portions of land, some of them not exceeding an acre in extent, and most of them less than four acres, where, in miserable hovels, barely sheltered, they labour in the fields, and subsist themselves and their families on half the produce of the land, the other half being delivered to the proprietor at the time of harvest as his rent. Their food, simple as it is, is far from being sufficient to keep them in a healthy state. They taste neither bread nor animal food. Their chief subsistence is called polenta, made from Indian corn, which is merely pounded and then boiled, no expense on account of the miller or the baker being incurred. This kind of meal, made to the consistence of hasty pudding, would certainly be an aliment sufficient to support life when the quantity could be adequately supplied; but, with the utmost parsimony during the whole year, the termination of it, as the next harvest approaches, often finds them utterly destitute, and with no other resource but beggary or starvation. This is the condition of the larger class of human beings in the north and middle of Italy; whilst in the south the lazzaroni of Naples are living proofs of the wretched condition of great numbers in that more fertile soil and more temperate climate.

The Italians as a nation, excepting, however, those of the lowest class, are a fine race of men. The men are well formed, rather slim than stout, but strong and agile, with a complexion, either from nature or from exposure to the sun, of a dark hue, with expressive countenances and dark sparkling eyes, and for the most part with black hair. Their gait is grave but not solemn, and their whole appearance is expressive of self-respect. The women have mostly narrow foreheads, black or dark-brown hair, large, brilliant, and expressive eyes, a beautiful nose, which, with the forehead, forms the elegant Roman profile; a small mouth, with lips rather swelling; a clear, white complexion, with slight red tinges showing through it, and a delicate but well-formed figure. But the lower classes, owing to their early marriages, their subsisting wholly on vegetable food, and the hard labour they endure, exposed to a burning sun, have their beauty checked before it has attained maturity, and rarely display any attractions.

A hasty or an unobservant traveller, in passing through Italy, may well be charmed with the scenery of the country, the magnificence of the cities, the clearness of the sky, and the mildness of the climate. He will see only what is admirable and exciting. The prospects on descending from the Alps, adorned as they are by lofty precipices, with their tops buried in snow, and their sides discovering waterfalls descending into the beautiful lakes below, are all of a kind to gratify the sense, as are also the odours exhaled from flowers; and the fruit-trees regale another sense at the bottom. On the plains, too, the beauty of the fields, surrounded with mulberry trees, having vines in elegant festoons, with their pendant fruit, trained from one tree to the next, the centre of the enclosure exhibiting heavy crops of corn, pulse, or culinary vegetables, all conspire to increase the delight. The excellence of the roads, the post-horses, and the inns, contribute their share to heighten the enjoyment. The appearance, too, of the cities, with their magnificent public edifices and their spacious private dwellings, though the streets may be narrow and crooked, presents a picture eminently calculated to convey to the beholder that feeling of pleasure which novelty usually creates in the mind. We have enjoyed these gratifications to the fullest extent; but, in the description here given, we have felt it a duty to look beyond the delightful surface, to view the interior of the land, the state of the several classes of society that inhabit it, and to communicate to the reader the most accurate view that could be produced after much careful investigation. If it be more dark and gloomy than it has been commonly drawn, it will not be found, by those who, like the writer, have examined and discriminated, to be unfaithful in the delineation.

In every country agriculture is the chief branch of industry, and this is eminently the case in Italy; but, from the formation of the land, and still more from its extending through ten degrees of latitude, it becomes difficult to take a general view of the state of cultivation. The cultivation of Savoy or Lombardy differs from that of Calabria as much as that of Massachusetts does from that of Carolina. In this work, therefore, the details of rural economy will be found under the heads of the several dominions into which Italy is divided; and in this place will only be noticed those results of agriculture which yield food, drink, or clothing to its inhabitants, or which form the basis of manufacturing industry, or the rudiments of foreign commerce. The cerealia form, as elsewhere in Europe, the chief aliment of the inhabitants; in Italy, however, the lower classes, who are the most numerous, subsist much on maize, which requires little preparation to render it fit for food. In some of the southern parts wheat is made use of by the same class, not in the form of bread, but in that of macaroni, which is manipulated with greater facility. It is made from a hard wheat commonly produced from the soil, or, in times of scarcity, imported from the countries on the Black Sea or the Sea of Azoph. Wheat and maize are, on the average of years, about equal to the consumption, but little or none can be spared for exportation; and in many of the ports are depôts of foreign wheat kept to meet the variations of seasons, or to be used as articles of commerce with other countries.

As Italy produces abundance of wine, and consequently needs neither beer nor corn-spirits, no barley is needed for these drinks, and scarcely any is cultivated. Oats are but little grown, but abundance of beans of various kinds is produced. Rye, the common bread-corn of the far greater portion of Europe, is only raised in a few spots in the very northernmost parts of Italy, where it is made into bread for the poor; whilst those of the higher classes there, as well as throughout the whole peninsula in the cities, make use of wheaten bread. Rice grows in many parts, in fact wherever there is a sufficiency of water to insure a good produce, at such a distance from towns as not to be injurious to the health of the inhabitants. It is a part of almost every meal in families in easy circumstances, but is scarcely used by the families who are in circumstances that require the practice of great parsimony. A great variety of lupines are used as food, especially in the soups. In some parts of the mountainous regions chestnuts are a substitute for corn as long as they last. Fruits are plentifully used, particularly melons and cucumbers, as food; whilst the cheapness of onions, garlic, tomatos or love-apples, and capsicums, render them valuable as condiments. It is singular that that useful vegetable the potato, which in the other parts of Europe has been so much extended of late years, has been but partially introduced into Italy; and, where it is cultivated, it occupies a very small proportion of the soil. Lettuces, asparagus, endive, artichokes, and several kinds of turnips and of carrots, are everywhere grown.

Animal food is far from being extensively used. The oxen yield in some parts excellent, in others very indifferent, meat. The mutton is neither good nor abundant. Swine furnish a plentiful supply during the winter months, but are chiefly to be seen as bacon or hams, and above all prepared as sausages, the fame of which latter has reached unto England under the name of the city Bologna, where they were early and extensively prepared. The large dairy farms in Lombardy, in which the cheese known by the name of Parmesan is made, furnish the most and the best swine's flesh.

The fisheries contribute largely to the supply of food in Italy, though, from the number of fasts still countenanced by the Catholic church, not sufficient for the consumption; and the deficiency is procured by commerce with the English, French, and Americans, who convey to the sea-ports the salted cod-fish from the banks of Newfoundland. Their own fisheries on the coast give much occupation; the most considerable are those for the tunny, a very large fish, and for the anchovy, a very small one. These are conducted upon a large scale by joint-stock companies, composed of almost the whole of the inhabitants of the parts of the coast where they are carried on. The lakes and the rivers also yield some, though not a great proportion, of that kind of food which ecclesiastical restrictions render indispensable.

The sugar-cane is cultivated in the south of Italy, and some is grown spontaneously; but it is found, that in point of strength, as well as of cost, the sugar made from it does not succeed in a competition with that substance when imported from the West Indies.

The products of agriculture are sufficient for the clothing of all its inhabitants; for though wool is neither good nor plentiful, yet hemp and flax are grown everywhere, are manufactured at home, and, from the nature of the climate, linen can be substituted for woollen dress during most of the months of the year. Some raw wool is, however, imported to supply the manufactures, and some cloths both from England and France, together with (in Lombardy) those from the other Austrian provinces, especially from Bohemia. Some cotton is grown on the southern divisions of Italy, but not sufficient to furnish materials for their very insignificant institutions of that manufacture.

The chief product of Italian agriculture is the silk. It is produced in every part, and much of it is converted into articles of dress or of furniture, where it is collected; but the chief production of it is in the dominions of the king of Sardinia, or of the emperor of Austria, whence the looms of England, Prussia, Austria, Russia, and Germany, are supplied. The value of this commodity exceeds that of all the other productions of Italy which are exported to foreign countries. It is still making, as it has made during the last eighteen years, a rapid advance; and the great increase which has taken place in the propagation of mulberry trees promises, as they arrive at maturity, to increase the quantity of raw silk to an extent which could not have been calculated upon twenty years ago. An enlargement on this important article of commerce would be out of place in this general account of Italy; and for further information on the subject the reader is referred to the articles LOMBARDY and PIEDMONT in this work.

An article of great importance, produced from the soil of Italy, which is used partly as food, partly employed in home manufactures, and extensively exported as an article of foreign commerce, is the oil of the olive tree. It is used as a substitute for butter in the south, is much appropriated to the manufacture of many kinds of soap, and is exported to England for the use of our various fabrics, chiefly those of wool, and as a luxury at our tables. The planting and watching costs but little labour or expense, and in a few years the income more than recompenses for the labour. The best olive oil is produced near Genoa, in Lucca, in Tuscany, and in Calabria; but it is plentiful throughout the whole of Italy, except in Lombardy and in Piedmont.

The wines of Italy are not very highly valued in other countries, and almost the whole that is produced is consumed at home. In the northern parts there is a degree of acidity unfavourable to the taste, and scarcely any of them are or can be preserved beyond one year. The vines are not so much grown in vineyards, as in the hedge-rows; and this, it is thought, injures the quality of the wine. In the southern parts the wines are of a more fiery quality, but are not much esteemed by foreigners. The names of them will be found under the articles TUSCANY, NAPLES, SICILY, and PAPAL DOMINIONS. The grapes are in some of the southern states dried into raisins, as an article of foreign commerce; but the whole is an insignificant branch of trade.

The minerals of Italy are of small amount; and though mines of gold, silver, and copper were once wrought, all of them are now extinct. It yields at present some alum in the Papal Dominions and the Neapolitan territory, some vitriol and antimony in Parma, and sulphur in the kingdom of Naples. In many parts marble is extracted, but the best is near Verona and Carrara; and alabaster is found in many of the mountains. The salt is furnished on the sea-shore, and some of it from saline springs, and is adequate to the consumption.

The foreign commerce of Italy, and the internal trade, as well as the manufacturing industry, are various in the different states, and are or will be noticed in their appropriate places in this work. It need only be said here, that the roads being good in Italy, the intercourse between the several states is kept up with great facility; and that the interchange of the commodities of one district with those of another is profitable to those trading classes generally who devote themselves to the occupation. (G.)

ITCH, a cutaneous disease, appearing in small watery pustules on the skin, and commonly of a mild nature, though sometimes attended with obstinate and dangerous symptoms. See MEDICINE, *Index.*

Itch-Insect. See ACARUS, ENTOMOLOGY, *Index.*

In speaking of the manner of finding these insects in the itch, Fabricius observes, that the failure of many who have sought for them has been owing to their having expected to meet with them in the larger vesicles, containing a yellowish fluid like pus: in these he informs us he never found them, but only in those pustules which were recent, and contained merely a watery fluid. We must therefore, he observes, not expect to find them in the same proportional number in patients who for many months have been afflicted with the disease, as in those in whom its appearance is recent, and where it is confined to the fingers or wrists. The cause of this difference with respect to the pustules may, he conjectures, be owing to the death of the insect after it has deposited its eggs. A small transparent vesicle being found, a very minute white point, distinct from the surrounding fluid, may be discovered, and very often even without the assistance of a glass. This is the insect, which may be easily taken out on the point of a needle or penknife, and when placed on a green cloth may be seen much more distinctly, and observed to move. But all this, we may observe, probably depends on some optical deception.

ITCHAPOUR, a town of Hindustan, in the Northern Circars, thirty miles south-west from Ganjam.

ITEA, a genus of plants belonging to the pentandria class. See BOTANY, *Index.*

ITHACA, in *Ancient Geography,* an island in the Ionian Sea, on the coast of Epirus, the country of Ulysses, with a town and port situated at the foot of Mount Neius. According to Pliny, it is about twenty-five miles in compass, and according to Artemidorus only ten; but it is now found to be seventeen miles long and four broad. See article IONIAN ISLES.

ITINERARY, ITINERARIUM, a journal of travels, or an account of the distances of places. The most remarkable itinerary is that which goes under the names of *Antoninus* and *Æthicus,* or, as Barthius found in his copy, *Antoninus Æthicus;* a Christian writer, posterior to the times of Constantine. There is another itinerary, called *Hierosolymitanum,* from Bordeaux to Jerusalem, and from Heraclea through Aulona and Rome to Milan, under Constantine. The word *Itinerarium* denotes a day's march.

ITIUS PORTUS, in *Ancient Geography,* the *crux geographorum,* so called from the difficulty of ascertaining its position. It would be endless to recite the different opinions concerning it, with the various reasons advanced in support of them. Three ports are mentioned by Cæsar, two of them without any particular name, viz. the higher and the lower with respect to the *Portus Itius.* Calais, Boulogne, St Omer, and Whitsand, have each in its turn had its several advocates. Cæsar gives two distinctive characters or marks which seem to apply equally to Boulogne and Whitsand, namely, the shortness of the passage, and the situation between two other ports; therefore nothing can be determined with certainty respecting the situation of the *Portus Itius.*

ITURUP, one of the Kurile Islands, on which the Japanese some years since made a settlement. The Russians attacked them in 1807, and returned with considerable booty to Kamtschatka, whence they had sailed with two vessels.

ITYS, in fabulous history, a son of Tereus king of Thrace, by Procne, daughter of Pandion king of Athens. He was killed by his mother when he was about six years old, and served up before his father. He was changed into a pheasant, his mother into a swallow, and his father into an owl.

ITZECUINTEPOTZOTLI, or HUNCH-BACKED DOG, a Mexican quadruped similar to a dog. It is as large as a Maltese dog, the skin of which is varied with white, tawny, and black. The characteristic mark is a great hunch which it bears from its neck to its rump. This animal abounds most in the kingdom of Michuacan.

ITZEHOE, a town of Denmark, in the province of Holstein, situated on the navigable river Stor, in a pleasant valley. It contains 513 houses, and about 4000 inhabitants, who carry on an extensive trade in corn, and fit out many ships for the Greenland whale-fishery. Long. 9. 26. E. Lat. 53. 56. N.

IULUS, a son of Ascanius, born in Lavinium. In the succession to the kingdom of Alba, Æneas Sylvius, the son of Æneas and Lavinia, was preferred to him. But he was, by way of compensation, made chief priest.

Iulus, a genus of insects of the order aptera. See Entomology, *Index*.

IVA, a genus of plants belonging to the monœcia class, and in the natural method ranking under the fourth order, *Compositæ*. See Botany, *Index*.

IVAHAH, the name of a canoe employed by the South Sea islanders for making short excursions to sea. It is wall-sided, flat bottomed, and of different sizes, varying from seventy-two feet to ten; but its breadth is by no means in proportion; for canoes of ten feet are about a foot wide, and those of more than seventy are scarcely two. The fighting ivahah is the longest, and has its head and stern considerably raised. The fishing ivahahs are from ten to forty feet in length; those of twenty-five feet and upwards occasionally carry sail. The travelling ivahah is always double, and furnished with a small neat house.

IVER, a town of the county of Buckingham, in the hundred of Stoke, eighteen miles from London. It stands on the river Colme, which turns several corn and some spinning mills. The population amounted in 1801 to 1377, in 1811 to 1635, in 1821 to 1663, and in 1831 to 1870.

IVES, St, a borough and market-town of the county of Cornwall, in the hundred of Penwith, 276 miles from London. It is a sea-port, on the west side of the bay of that name, on the Bristol Channel. The government is in a mayor, twelve capital and twenty-four inferior burgesses. It returns two members to the House of Commons, chosen by the householders. The inhabitants amounted in 1801 to 2714, in 1811 to 3281, in 1821 to 3526, and in 1831 to 4776.

Ives, *St*, a market-town of the county of Huntingdon, in the hundred of Hurstingstone, sixty miles from London. It is in a rich plain, through which the navigable river Ouse flows, and is a well-built town, with a good market on Monday. The inhabitants amounted in 1801 to 2099, in 1811 to 2426, in 1821 to 2777, and in 1831 to 3314.

IVISA, or IVICA, one of the Balearic Islands, in the Mediterranean Sea, belonging to the crown of Spain. Its inhabitants amount to 15,200. It is about sixteen leagues to the eastward of Cape St Antonia, on the coast of Valencia. Its figure is an irregular polygon, stretching from north-west to south-east twenty-eight miles, and being in breadth fourteen miles. Its capital, of the same name, forms a good port, and is very well fortified. It is well built, and contains, including the suburb called Marina, about 3500 inhabitants. It yields wheat, oil, wine, flax, hemp, figs, almonds, raisins, oranges, lemons, cotton, and esparto, which are exported; but its principal commerce is in salt, which is most copiously formed in the various salt lagunes which surround the coast of the island. There are yearly produced from 130,000 to 170,000 cwts. The inhabitants are more attached to fishing than to agriculture, and the greater portion of the men follow that employment, leaving the care of cultivation to the females, who are robust and industrious. The capital is situated in north latitude 38. 53. 16. and east longitude from London 1. 57. 56.

IVINGHOE, a market-town of the county of Buckingham, in the hundred of Cotslow, thirty-six miles from London. The town is pleasantly situated on the side of a hill, with an extensive prospect over a rich valley. The inhabitants amounted in 1801 to 452, in 1811 to 508, in 1821 to 551, and in 1831 to 573.

IVORY is the name given to the tusks of the elephant, and of the walrus or sea-horse. Each male elephant arrived at maturity has two tusks. These are extremely diversified in size, which depends principally on the age of the animal; they are hollow at their insertion into the jaw and for a considerable space therefrom, and always taper to an obtuse extremity. The colour externally is yellowish, brownish, and sometimes dark, but internally it is a cream white. The best tusks are large, straight, and light coloured, without flaws; not very hollow in the stump, but, on the contrary, solid and thick. The most esteemed are obtained from Africa, being of a closer texture, and less liable to become yellow, than those imported from the East Indies. The tusks of the sea-horse afford the hardest and whitest of all ivory. They are usually short, and very much curved; the thick end is hollow, as in the tusk of the elephant; a glossy enamel of extreme hardness covers the cortical part; and they vary in weight from three or four pounds to thirty. The horn or tooth of the narwhal, one of the cetaceous tribe, also consists of ivory, which is as hard as that of the elephant, and susceptible of a fine polish. The largest size is ten feet in length, and some inches thick at the lower extremity, forming a slender cone of a twisted or spiral figure. But its texture is in several respects different from that of other ivory; and there is a prejudice against the ordinary use of it amongst those who work in that material.

From the earliest times, the people of all the Asiatic countries, where the elephant is found, have had the art of taming the animal, and applying it to useful purposes; but no such art has ever been possessed by any African nation. Nor has this apparently been owing to any difference between the Asiatic and African elephant in point of docility; the real cause is probably to be found in the inferior intelligence and sagacity of the African people. Alexander the Great is believed to have been the first European who employed elephants in war. With regard to those made use of by the Carthaginians, it has been supposed, though with little probability, that they were mostly, if not wholly, imported from India, and that they were managed by Indian conductors, some of whom were captured by the Romans in the great victory gained by Metellus over Asdrubal. But, in the first place, the name of Indian, as used by the Romans, was so extremely vague, that no safe conclusion can be drawn from it; nor, even if the conductors were of that people, does it follow that the elephants had been brought from India. And, secondly, it is not reasonable to suppose that an active and enterprising people, like the Carthaginians, would have imported from a distant country, and at an enormous expense, an animal which, they must have known, was to be found in equal vigour and perfection in their own. On this subject, however, we beg to refer the reader to some learned and valuable notes in the *Ancient Universal History* (vol. xvii. p. 529, 8vo); and also to Buffon's article on the elephant, one of the most masterly pieces of composition to be found in his admirable work.

Ivory is applied to a variety of purposes in the arts. In England, the chief consumption of that commodity is in the manufacture of handles for knives; but it is also extensively used in the manufacture of musical and mathematical instruments, chess-pieces, billiard-balls, thin plates for miniatures, toys, and small works of vertù. Articles in ivory, however, are said to be manufactured to a greater extent, and with much more success, at Dieppe, than at any other place in Europe. But the art of working in this beautiful material is far better understood by the Chinese than by any other nation. No European artist has hitherto succeeded in cutting concentric balls after the manner of this people; nor have their boxes, chess-pieces, and other articles manufactured in ivory, been approached, far less rivalled, by any similar productions that are to be met with in other countries.

Ivory, in the rough state, is a very considerable article of commerce. The importation of elephants' tusks into Great Britain, for twelve years from 1788 to 1799 inclusively, amounted to 18,914 cwts. or, on an average, to 1576 cwts. annually. Since that period, however, the trade has much increased. The imports in 1831 and 1832 were, at an average, 4130 cwts., of which 2950 cwts. were retained for home consumption. But as the medium weight of a tusk is about sixty lbs. it follows that the yearly imports of 1831 and 1832 must be taken at 7709 tusks, and that, to obtain these, 3854 male elephants must have been destroyed. But, supposing the tusks could only be obtained by killing the animal, the destruction would really be a good deal greater, and must probably have amounted to 4500 or 5000 elephants. Occasionally, however, tusks are accidentally broken, one lost in this way being replaced by a new one; and a good many are also obtained from elephants which have died a natural death. Still it is obvious that the supply from these sources cannot be very large; and if to the quantity of ivory required for Great Britain be added that required for the other countries of Europe, as well as for America and Asia, the slaughter of elephants must, after every deduction, be immense; nor can it fail to excite surprise that the breed of this magnificent animal, and consequently the supply of tusks, has not been more diminished. The western and eastern coasts of Africa, the Cape of Good Hope, Ceylon, India, and the countries to the eastward of the Straits of Malacca, are the great marts whence supplies of ivory are obtained. The imports into Great Britain from Western Africa in 1831 amounted to 2575 cwts. whilst the Cape of Good Hope only furnished 198 cwts. During the same year, the imports from India, Ceylon, and other eastern countries, amounted to 2173 cwts. The price per cwt. duty (L.1 per cwt.) included, of elephants' tusks in the London market, in December 1833, was as follows:—

1st sort, weighing from	79 to 90 lbs. per tusk	L.29	0	0	to	L.31	0	0
2d do.	56 to 60	25	0	0	to	23	0	0
3d do.	38 to 55	23	0	0	to	26	0	0
4th do.	28 to 37	20	0	0	to	24	0	0
5th do.	18 to 27	18	0	0	to	21	0	0
Scrivelloes		14	0	0	to	35	0	0
Sea-horse teeth						5	0	0

(A.)

IVRY, a market-town of the arrondissement of Evereux, in the department of the Eure, in France, remarkable for the victory gained there by Henry IV. over the Duke of Mayenne in 1590. It is situated on the banks of the Eure, and contains about 1250 inhabitants, who are occupied in tanneries, and in twist spinning.

IVY. See HEDERA, BOTANY, *Index*.

IXIA, a genus of plants belonging to the triandria class, and in the natural method ranking under the sixth order, *Ensatæ*. See BOTANY, *Index*.

IXION, in fabulous history, the king of the Lapithæ, who, having married Dia, the daughter of Deionius, refused to give her the customary nuptial presents. Deionius in revenge took from him his horses; when Ixion, dissembling his resentment, invited his father-in-law to a feast, and contrived that the latter should fall through a trap-door into a burning furnace, in which he was immediately consumed. Ixion being afterwards stung with remorse for his cruelty, ran mad; upon which Jupiter, in compassion, not only forgave him, but took him up into heaven, where he had the impiety to endeavour to seduce Juno. Jupiter, to be assured of his guilt, formed a cloud in the resemblance of the goddess, upon which Ixion begat the centaurs; but having boasted of his happiness, Jove hurled him down to Tartarus, where he remains fixed on an ever-revolving wheel encompassed with serpents.

IXORA, a genus of plants belonging to the tetrandria class, and in the natural method ranking under the forty-seventh order, *Stellatæ*. See BOTANY, *Index*.

IXWORTH, a market-town of the county of Suffolk, in the hundred of Blackburn, seventy-seven miles from London. It is a neat town, with a market on Friday. The inhabitants amounted in 1801 to 827, in 1811 to 846, in 1821 to 952, and in 1831 to 1061.

JABESH, or *Jabesh Gilead*, was the name of a city in the half tribe of Manasseh, beyond Jordan. The Scripture calls it generally Jabesh Gilead, because it lay in Gilead, at the foot of the mountains which go by this name. Eusebius places it six miles from Pella, towards Gerasa; and hence it must have been to the eastward of the Sea of Tiberias.

JABLONKA, a town of the circle of Trentsin, in the Austrian kingdom of Hungary, celebrated for an extensive linen manufactory, containing 3580 inhabitants.

JABLONSKI, Daniel-Ernest, a learned Polish protestant divine, was born at Dantzig, on the 20th of November 1660. He commenced his studies at the gymnasium of Lissa, then attended the academical course of the university of Frankfort, and, after taking his degrees, visited Holland and England, in which last country he remained a year to hear the prelections of the Oxford professors. On his return he became successively minister of Magdeburg, Lissa, Köningsberg, and Berlin; and was at length appointed ecclesiastical counsellor, and president of the Academy of Sciences at Berlin. He took great pains to effect an union between the Lutherans and Calvinists, and wrote some works which are esteemed. He died in 1741. His works consist of, 1. A German and Hebrew Catechism, 1708, in 4to; 2. Sermons in German, 1718, in 4to; 3. The History of the *Consensus* of Sendomir, in Latin, 1730; 4. Different writings, in Latin and German, in favour of the Protestants of Poland, amongst which may be mentioned, Afflicted Thorn, or a Relation of what passed in that City since the 16th of July 1724, of which there is a French translation by Beausobre, Amsterdam, 1726, in 12mo, now very rare.

Jablonski, *Paul-Ernest*, was the son of Daniel-Ernest, and, like his father, entered the clerical profession, but distinguished himself much more in that of instruction, and particularly in the study of the oriental literature and antiquities. Born at Berlin in the year 1695, he received his academical education at the university of Frankfort-on-the-Oder; and such was his progress in the study of the Coptic, that he even surpassed his master, the celebrated Lacroze. In 1714, being then only twenty-one years of age, he obtained permission to travel, at the king's expense, throughout the greater part of Europe, in order to extend his knowledge of that language. He visited the rich libraries of Oxford, Leyden, and Paris, and made ample extracts from all the Coptic manuscripts which were then contained in these collections. On his return to his own country, he was appointed pastor of Liebenberg, in the Middle March, in 1720; professor of philosophy in 1721; ordinary professor of theology at Frankfort-on-the-Oder, and pastor of the Reformed or Calvinistic congregation of the same city, in 1722; and, not long afterwards, member of the Academy of Sciences of Berlin. This learned antiquary and orientalist died on the 13th of September 1757, after having published more than fifty works, of which a list may be found in the Dictionary of Meusel. Of these the principal are, 1. Disquisitio de Lingua Lycaonica, Berlin, 1714, in 4to; 2. Thirty-nine Letters full of erudition, in the *Thesaurus Epistolic. Lacrozianus*, tom. i. p. 163 et seqq.; 3. Exercitatio Historico-theologica de Nestorianismo, Berlin, 1724, in 8vo; 4. Remphah Egyptiorum Deus ab Israëlitis in deserto cultus, Frankfort, 1731, in 8vo; 5. Dissertationes Academicæ viii. de terra Gosen, ibid. 1735, 1736, in 4to; 6. De ultimis Pauli Apostoli laboribus a B. Luca prætermissis, ibid. 1746, in 4to; 7. Pantheon Ægyptiorum, sive de Diis eorum Commentarius, cum Prolegomenis de Religione et Theologia Ægyptiorum, ibid. 1750, 1752, in 3 vols. 8vo; 8. De Memnone Græcorum et Ægyptiorum, hujusque celeberrima in Thebaïde statua, ibid. 1753, in 4to, with figures; 9. Institutiones Historiæ Christianæ antiquioris, ibid. 1754, in 8vo; 10. Institutiones Historiæ Christianæ recentioris, ibid. 1756, in 8vo; 11. Remarks on the Canon of the Kings of Thebes, by Eratosthenes, inserted in the Chronology of Devignoles; 12. Different Memoirs or Extracts in the *Miscellanea Berolinensia*, the *Nova Miscellanea Lipsiensia*, and other periodical collections; and, 13. Opuscula quibus Lingua et Antiquitas Ægyptiorum, difficilia Librorum Sacrorum loca, et Historiæ Ecclesiasticæ capita illustrantur, magnam partem nunc primum in lucem protracta, edidit Jan. Gulielm. Te-Water, Leyden, 1804, 1813, in 4 vols. 8vo.

Of all the works of Jablonski, undoubtedly the most important is his *Pantheon Ægyptiorum*, and it is also the most complete treatise we possess on the subject to which it relates. For, although subsequent investigations, and monuments recently discovered, may have shed new light on different matters of detail, the estimation in which the work as a whole is held by the learned has not on that account been diminished. But, to peruse it with advantage, the reader should begin with the *Prolegomena*, which are commonly annexed to the second or third volume. Jablonski had commenced this work as early as the year 1720; and he is sometimes censured for having made no use of what appeared on the same subject in the interval between that year and the date of its completion. His own resources, however, were great; and although the general table at the end of the third volume occupies twenty-nine pages, some critics have found it of too limited extent in proportion to the variety of materials and the vast erudition displayed in the work. Jablonski is merely the translator into Latin of what relates to the worship of the sacred animals; he acknowledges, indeed, that this piece had been furnished to him by a lady of high rank, "matrona perillustris, non natalium magis et dignitatis splendore quam virtute incomparabili et raræ doctrinæ inclyta;" but he gives no information which can enable us to ascertain who this distinguished female really was. His treatise on the Memnon of the Greeks and Egyptians, and on the celebrated statue in the Thebaid, is a sort of sequel to the *Pantheon*, and, like it, is full of erudition. In his dissertation on the Egyptian god Remphah, worshipped by the Israelites in the desert, he proves, from Egyptian and Coptic monuments, what the very name of the god might have led him to infer, that Remphah is the same with the Sun, which, in Egyptian, is denominated Ra, Ré, and Phré. To the student of Egyptian antiquities, and particularly of Coptic, the *Opuscula* present many recommendations, not only as being a collection of valuable pieces, some of which had been published separately, whilst others had remained in manuscript, and all equally inaccessible to scholars generally, but also as containing the fruits of the author's mature labours, especially a valuable glossary of Egyptian words, whether found in the Bible or in the ancient Greek and Latin authors. The treatise on the Statue of Memnon has been translated into French by M. Langlés, who has inserted it, with several additions, in the second volume of his translation of the Travels of Norden. (A.)

Jablonski, *Theodore*, counsellor of the court of Prussia, and secretary of the Royal Academy of Sciences in Berlin, was also a man of distinguished merit. He loved the sciences, and did them honour, without that ambition which is generally observable in men of learning; and it was owing to this modesty that the greatest part of his works were published without his name. He published, in 1711, a French and German Dictionary; in 1713, a Course of Morality; a Dictionary of Arts and Sciences in 1721; and translated *Tacitus de Moribus Germanorum* into High Dutch in 1724.

JACA, a city of Spain, in the province of Aragon. It is situated at the foot of the Pyrenees, near the river Aragon, from which the province has derived its name. The situation is on a plain of fertile land, between two lofty sierras. There are in it considerable manufactures of cloths and baizes. It is a place of great antiquity, and of considerable strength; the walls, of ancient date, are flanked with towers, and the citadel attached to it is capable of considerable resistance. It contains 4000 inhabitants, and is in longitude 0. 41. W. and latitude 42. 29. N.

JACATRA, a district of the island of Java, formerly a kingdom, governed by its own sovereigns. It was subdued by the Dutch East India Company's troops in the year 1619, who have ever since retained possession of it as sovereigns by right of conquest. Since that period Batavia has been constituted the capital. The country is watered by several rivers, which, however, are little better than rivulets in the dry season.

JACK, in *Mechanics*, a well-known instrument, of common use for raising great weights of any kind. The common kitchen-jack is a compound engine, where weight is the power applied to overcome the friction of the parts and the weight with which the spit is charged; and a steady and uniform motion is obtained by means of the fly.

Jack, in nautical language, a sort of flag or colours, displayed from a mast erected on the outer end of a ship's boltsprit. In the British navy the jack is nothing more than a small union flag, composed of the intersection of the red and white crosses; but in merchant ships this union is bordered with a red field.

Jack is also used for a horse or wooden frame to saw timber upon; for an instrument to pull off a pair of boots; for a great leathern pitcher to carry drink in; for a small bowl that serves as a mark at the exercise of bowling; and for a young pike.

Jack-Daw, the English name of a species of corvus. See Ornithology.

JACKAL, in *Zoology*. See Mammalia.

JACOB, the son of Isaac and Rebekah, was born in the year of the world 2168, and before Jesus Christ 1836. The history of this patriarch is given at large in the book of Genesis. He died in Egypt in the 147th year of his age. Joseph directed that the body should be embalmed, after the manner of the Egyptians; and there was a general mourning for him throughout Egypt for seventy days. After this, Joseph and his brethren, accompanied by the principal men of Egypt, carried him, with the king of Egypt's permission, to the burying-place of his fathers, near Hebron, where his wife Leah had been interred. When they had reached the land of Canaan, they mourned for him again seven days; upon which occasion the place where they staid was called Abelmisraim, or the mourning of the Egyptians.

Jacob, *Ben Hajim*, a rabbi famous for the collection of the Masorah in 1525, together with the text of the Bible, the Chaldaic paraphrase, and the Rabbinical commentaries.

Jacob, *Ben Naphtali*, a famous rabbi of the fifth century. He was one of the principal masorets, and bred at the school of Tiberias in Palestine, with Ben Aser, another masoret. The invention of points in Hebrew to serve for vowels, and of accents to facilitate the reading of the language, are ascribed by some to these two rabbin; and said to be introduced in an assembly of the Jews held at Tiberias, A. D. 476.

JACOBIN Monks, the same with Dominicans.

Jacobins, the name assumed by a party or club at the beginning of the French revolution, composed of members of the National Assembly. The club held its meetings in the hall belonging to the Jacobin friars, and from the place of assemblage derived its name.

JACOBITES, a term of reproach, in England, bestowed on the persons who, vindicating the doctrines of passive obedience and non-resistance with respect to the arbitrary proceedings of princes, disavowed the revolution in 1688, and asserted the supposed rights of King James and his family.

Jacobites, in *Ecclesiastical History*, a seet of Christians in Syria and Mesopotamia, and so called, either from Jacob a Syrian, who lived in the reign of the Emperor Mauritius, or from one Jacob, a monk, who flourished in the year 550. The Jacobites were of two sects, some following the rites of the Latin church, and others continuing separated from that church. There is also a division amongst the latter, who have two rival patriarchs. As to their belief, they hold but one nature in Jesus Christ; with respect to purgatory and prayers for the dead, they are of the same opinion with the Greeks and other eastern Christians; they consecrate unleavened bread at the eucharist, and are against confession, believing that it is not of divine institution.

JACOBSTADT, a town of Russian Finland, and capital of the circle of Korsholm, stands on the sea-shore, and contains 218 houses, with 1250 inhabitants. Long. 22. 27. E. Lat. 63. 31. 8. N.

JACOBUS, a gold coin, worth twenty-five shillings, and so called from King James I. of England, in whose reign it was struck. There are two kinds of *Jacobus*, the old and the new; the former valued at twenty-five shillings, weighing six pennyweights ten grains; the latter, called also *Carolus*, valued at twenty-three shillings, and in weight five pennyweights twenty grains.

JACOTTA, a small town on the sea-coast of the province of Cochin. It is a fortified place, with a small harbour, where it is said St Thomas the apostle first landed from Africa. Long. 76. 1. E. Lat. 0. 14. S.

JACTALI, a town of Hindustan, belonging to the nizam, in the province of Hyderabad. Long. 79. 32. E. Lat. 18. 48. N.

JAEN, an ancient kingdom of the south of Spain, now forming one of the four portions into which the province of Andalusia is divided. The extent of this province is 268 square leagues, and its population amounts to 206,807 souls. La Mancha bounds it on the north, Cordova on the west, and Granada on the east and south. It is surrounded on every side by lofty mountains, which almost exclude it from intercourse with the surrounding provinces. Its surface is a constant alternation of hills and valleys; and as from the surrounding mountains innumerable rivulets issue, its lower levels of land are abundantly irrigated, and therefore highly productive, whilst the hills, from want of moisture, are barren, or yield little except some sheep pasture in the winter season, when the merino flocks, driven from the north, seek food in the southern provinces. It produces wheat and barley, but not sufficient for its consumption. It has abundance of oil, and a full supply of wine, and its fruits are exquisite and plentiful.

The principal river is the Guadalquivir, which runs through the centre of the province, and receives additions to its copious stream from the junction of the Guadalimar, the Jandula, the Jaen, and the Escobar. There are some mines of lead in this province, in which sometimes considerable quantities of silver are found. These mines were of some celebrity whilst the Romans governed Spain; and though the silver has been less sought for since the discovery of the mines of America, yet, for the sake of the lead, they are now carried on by the government, and furnish sheet lead, shot, and musket balls, to the southern part of the kingdom. The manufacture of earthen jars, called alcarrazas, for keeping liquors in a cool state in the warmest weather, is the most considerable production of Jaen that is sent out of the province; and they are much esteemed in every part of Andalusia. The celebrated university of Alcala la Real, founded by Cardinal Ximenes, still exists in this province, and is attended by a number of students in divinity. The biblical scholar recognises it as having been the scene of the labours of the editors of the Complutensian edition of the Old Testament. In this province is the celebrated field, called the Plain of Tolosa, on which, six centuries ago, the most sanguinary battle was fought that the history of Spain has recorded.

Jaen, a city of Spain, capital of the ancient kingdom of the same name, in latitude 37. 48. and now forming one of the divisions of Andalusia, is situated on the declivity of a mountain, between some lofty sierras, in a fertile and productive country, which yields some wine and abundance of oil, for which there are twenty-seven mills. It stands on the left bank of a small river, now of the same name, but called by the Moors Guadalbullon, which, after proceeding about six leagues beyond this city, falls into the Guadalquivir below Mengibar. The city is deemed very healthy. The situation being elevated about 1400 feet above the level of the sea, renders it temperate; and the sierras which surround it, by the breezes that descend from them, tend to refresh the air in the most sultry seasons. The inhabitants amount to about 9000, who are not distinguished by their industry; and the only manufactures that are carried on are those of leather and soap. It is a bishop's see; and the cathedral, of great antiquity, has no peculiar beauty to render it deserving of notice.

JAFFIERABAD, a town of Hindustan, in the province of Berar, twenty-four miles north from Jalnapoor. Long. 76. 36. E. Lat. 20. 17. N.

JAFFRABAT, a town of Hindustan, on the sea-coast of the Gujerat peninsula, on the banks of a shallow river. It was formerly a place of considerable commerce, but is now possessed by native chiefs. Long. 71. 31. E. Lat. 20. 53. N.

JAFNA, the capital of the district of Jafnapatam. It stands at some distance from the sea, but communicates with it by a river navigable for large boats, and which falls into the sea near Point Pedro. The town is fortified, and possesses a good citadel, which, though small, is exceedingly well built; but it was given up in 1795, after a short resistance, to the British troops. The situation is salubrious, and living is cheap; on which account many families have removed to this place from Columbo. The greater part of the inhabitants are of Mahommedan extraction, and are divided into several tribes, known by the names of Lubbahs, Moplays, Chittees, and Cholias. The foreign settlers are more numerous than the native inhabitants. There are manufactures of coarse cotton cloths, calicoes, handkerchiefs, shawls, stockings, &c.; and there are also many artificers, such as goldsmiths, jewellers, joiners, and cabinet-makers.

JAFNAPATAM is the name of a district in the northern extremity of Ceylon. It is considered as the most healthy and populous part of the island, as it escapes, owing to its maritime situation, the intensely hot winds which prevail on the continent. It is clear of woods, produces a variety of fruit and vegetables, and abounds also in poultry and game; whilst the tract that lies between Point Pedro and Jafna is favourable to the breeding of sheep. In the islands dependent on this district, namely, Delft, Harlem, Leyden, and Amsterdam, so named by the Dutch from their native cities, government has an establishment for breeding horses and cattle, for which the islands afford excellent pasture. The woods towards the interior, separating the district from the Candian provinces, are inhabited by a savage race of people known by the name of the Vadahs or Bedahs, who are supposed to be the ancient inhabitants of the country.

JAGEPOOR, a large straggling town of Hindustan, in the province of Cuttack, situated on the south side of the Byturnee River, which is here nearly half a mile broad. It is the chief town of a principality of the same name, and has a manufacture of cotton cloths. Here formerly resided an independent rajah, who, in the year 1243, repelled the Afghans from his territory, and, pursuing them into Bengal, laid siege to Gour, the ancient capital of that country. They were again totally defeated in the year 1263. We have no certain account of the time when this country fell into the power of the Mahommedans, by whom it was possessed until it was conquered by the Mahrattas. During the period of the Mogul government it was a place of some consequence, and the remains of several Mahommedan mosques and other edifices are still visible. In the year 1751 it was ceded to the Mahrattas, under whose government it has declined; but it will probably recover, since the province has been subjected to the authority of Britain. Long. 86. 35. E. Lat. 20. 50. N.

JAGERNDORF, or, in the Sclavonic, Karnou, a city of the Austrian province of Moravia, situated on the river Oppa. It is surrounded with high walls, contains two colleges, the castle of the Lobenstein family, and 538 houses, with 4590 inhabitants, who are occupied in manufacturing linen and woollen goods of various descriptions.

JAGERON, a river of Persia, which rises nearly 120 miles north-east of Casbin, and loses itself in a sandy desert after a course of 150 miles.

JAGGERNAUT. See Juggernaut.

JAGHIRE, a district of the Carnatic, now included in the collectorship of Chingleput. It extends northwards from Madras to the Pullicat Lake, southwards to Allumparva, and westwards beyond Conjeveram. It is about 108 miles along shore, and forty-seven inland in the widest part, containing altogether 2440 square miles. This territory was obtained in the years 1750 and 1763, from the nabob of Arcot, in return for services rendered to him and his father by the Company; and was rented to the nabob on renewed leases until 1780, when it was taken under the management of the presidency of St George. This territory was dreadfully ravaged by Hyder Ali in 1768, and in the war of 1780; and was left in a state almost desolate, with nothing to mark its former state but the bones of those who had been massacred, or the naked walls of houses, temples, &c. A destructive famine, which succeeded, completed the ruin of the country.

Jaghire, an assignment made in Bengal by an imperial grant upon the revenue of any district, to defray civil or military charges, pensions, gratuities, and the like.

JAGHIREDAR, the holder of a jaghire.

JAGO, Richard, an ingenious poet, was vicar of Snitterfield in Warwickshire, and rector of Kimcote in Leicestershire. He was the intimate friend and correspondent of Shenstone, who was his contemporary at Oxford, and also, it is believed, his school-fellow; he belonged to

University College, and took the degree of master of arts in 1739; and he was author of several poems in th fourth and fifth volumes of Dodsley's collection. He died on the 28th of May 1781.

JAGO, ST. See SANTIAGO.

JAGO, *St*, the name of several provinces, towns, and rivers of South America, which will be described under the heads of the several countries in which they occur.

JAGO, *St*, one of the Cape de Verde Islands. See VERDE ISLANDS, CAPE DE.

JAGRAAM, a town of Hindustan, in Delhi, belonging to the Seiks. Long. 75. E. Lat. 30. 47. N.

JAGUEER. See JAGHIRE.

JAGUEERDAR. See JAGHIREDAR.

JAHDE, a town of the circle of Neuenburg, in the duchy of Oldenburg, in Germany, on a navigable river of the same name, which empties itself into the sea about two miles below the town. It contains 307 houses, with 2160 inhabitants. Long. 8. 12. 43. E. Lat. 53. 20. 45. N.

JAHIL, a town of Hindustan, in the Rajpoot territories, in the province of Ajmeer, sixty-five miles west-northwest from Jyanagur. Long. 74. 38. E. Lat. 27. 9. N.

JAHJOW, a village of Hindustan, in the province of Agra, remarkable for two great battles fought near it; the first on the 8th of June 1658, in which Aurungzebe was totally defeated; and the last on the 19th of June 1707, between the son and grandson of Aurungzebe, in which the latter was slain.

JAILLIEU, a town of the arrondissement of La Tour du Pin, in the department of the Isère, in France, on the river Bourbre. It contains 420 houses, and 1620 inhabitants, who are employed in paper-making and in calico-printing.

JAINS, called by some JOINUS, a sect or rather race of Hindus, found in considerable numbers in different parts of India, particularly in the southern peninsula. They form a class of dissenters from the established faith of Brahminism, so generally considered throughout India as alone founded on an orthodox basis. They deny altogether the authority of the Vedas, regarded by the genuine Hindu as the holiest of books. They either disown, or sink into a subordinate station, all the grand objects of Hindu veneration. In their hypothesis concerning the origin of the world, they have adopted opinions which seem to partake of the character of atheism. They do not, like the followers of the Vedas, acknowledge any spiritual and eternal Being, from whom the universe derived its origin. The material world, as well as the minds of all men and animals, are held by them to be eternal. They refuse to acknowledge anything which is not, or has not been, the object of the senses. Upon this principle they deny the existence of any beings superior to man, and admit no objects of worship except men who have raised themselves by their merits to the rank of divinities. As, however, they set no bounds to the perfection which the human soul may arrive at, their most eminent saints and pontiffs (amongst whom they particularly celebrate Gomat Iswara Swami) partake almost of the attributes of supreme divinity. To this station, however, they are exalted, not in consequence of a virtuous life, or of benefits rendered to mankind, but of those excesses of absurd and extravagant penance to which, throughout all India, such sovereign merit is attached. They have three ranks of ascetics, whom they call *Yatis*. The first, called *Anuvrata*, can be attained only by him who forsakes his family, entirely cuts off his hair, holds always in his hand a bundle of peacock's feathers and an earthen pot, and wears only clothes of a tawny colour. The second rank, *Mahavrata*, requires that all dress should be abandoned except a mere rag to cover nakedness, and that the hair instead of being shaven off, should be pulled out by the roots. He who aspires still higher, and seeks to attain the third degree, or *Nirvana*, throws aside even rags, and remains entirely naked; he eats nothing but rice, and that only once in two days. The name is nearly synonymous with that of Deity, and he is held in nearly equal veneration with the priests and rajahs, whose images are worshipped in the temples. At Billicull, or Belligola, the residence of their high priest, they have a gigantic image of Gomat Iswara Swami, the foot of which is nine feet in length, so that the height of the entire statue cannot be less than fifty-four feet; and there is a similar one at Kurcul, near Mangalore. This worship of gigantic images is common to them with the followers of Buddha, whom they also closely resemble in their theological tenets; nay, Samana and Gaudma, the main objects of Buddh veneration, are enumerated by the Jains amongst the earliest and most venerated of their priests. On the other hand, they differ from them entirely in being divided into four castes, distinguished from each other by the same privileges and manners as amongst other Hindus. The Jains observe also similar penances, carrying them only to a greater extreme. They are also scrupulous to a still greater degree as to causing the death of any living thing, even the minutest insect. The strictest Jains, to guard against this danger, do not eat after sunset; they have always a small broom to sweep the ground before them, and never drink water unless strained through a cloth. The orthodox Hindus have ceremonies by which any involuntary offence of this kind may be expiated; but the Jains, not allowing the efficacy of these, have no means of relieving their soul from the burden of such a trespass. Like the other Hindus, they consider it as unlawful for the widow to marry again, but discourage the barbarous practice of sacrificing herself on the body of the husband. On the whole, it would appear, that whilst their doctrines and belief closely coincide with those of the Buddhists, their civil and social life is discriminated only by minute shades from that of the Hindus. They have a system of their own with regard to history, chronology, and physics, of which we need only observe, that its tenets are still more extravagant and absurd than those contained in the orthodox pages of the Vedas and Puranas. (See *Asiatic Annual Register*, vol. ix.; Dubois *on the Manners of the People of India*, Lond. 1817; Ward *on the History, Literature, and Religion of the Hindus*, Lond. 1817.)

JAIVER, a town of Hindustan, in the province of Delhi, situated on the east side of the Jumna, forty-three miles south by east from Delhi. Long. 78. 28. E. Lat. 28. 9. N.

JAJARCOTE, a town of Hindustan, tributary to the Goorkhali rajah of Nepaul. Long. 81. 30. E. Lat. 29. 39. N.

JAJGHUR, a town of Hindustan, in the province of Ajmeer, and capital of a district of the same name. It formerly belonged to the rajah of Odeypoor, from whom it was taken by Zalim Singh, chief of Kotah, about the year 1803. The surrounding district comprehends eighty-four villages and towns, twenty-two of which are inhabited by a race of plunderers called Meenas, who give only personal service for their lands. The fort of Jajghur is built on the top of an oblong hill, and consists of two walls with ruined bastions, each having a ditch, and the outer wall lying a considerable way down the hill. The town is large, well built, and fortified.

JALEMUS, in *Antiquity*, a kind of mournful song, used upon occasion of death, or any other affecting occurrence. Hence originated the Greek proverbs, *ἰαλεμου ὀικρότερος*, or *ψυχρότερος, sadder or colder than a jalemus; ἐις τους ἰαλεμους ἐγγραπτεος, worthy to be ranked among jalemuses.*

JALOFFS, or YALLOFFS, a warlike people inhabiting that part of Africa lying between Senegal and the Mandingo states on the Gambia. See AFRICA.

JAMADAR, an officer of horse or foot, in Hindustan; also the head or superintendent of the peons in the sewaury or train of any great man.

JAMAICA.

Jamaica.

Jamaica, called *Xaymaca* by the Indians, and St Jago by the Spaniards, is the largest and most valuable island in the British West Indies. It is situated between the parallels of 17° 35′ and 18° 30′ north latitude, and of 76° and 78° 40′ west longitude, being one hundred and sixty miles in length by forty-five in breadth, and containing 4,000,000 acres of land. It lies ninety miles west of St Domingo, the same distance south of Cuba, four hundred and thirty-five miles north of Carthagena on the South American continent, and four thousand miles south-west of England.

Jamaica was discovered by Columbus on the 3d of May 1494, whilst coasting along the southern side of the island of Cuba, during his second voyage to the western world. It was found to be densely peopled by Indians, who opposed the landing of the Spaniards; but a discharge of arbalets put them to flight, and the discoverer formally took possession of the island in the name of his sovereign. His stay, however, was short, and for eight years the natives were allowed to remain in tranquil possession of their own territory. In 1503 was effected the first European settlement in Jamaica, and this was the result of necessity rather than of choice. During his fourth voyage, Columbus was forced, by stress of weather, to seek shelter on the northern side of the island, where he saved the lives of his exhausted comrades at the expense of the vessels, by running the latter ashore at a point called St Ann's Bay. Here for twelve months he endured great hardships and privations. He despatched a small squadron to Hispaniola, or Cuba as it is now called, for succours; but the governor of that island was his mortal enemy, and mocked his sufferings instead of alleviating them. A body of Spaniards also threw off their allegiance to their commander, and seizing on ten canoes which he had been preparing, put to sea in them, with the intention of crossing over to Hispaniola; but a storm forced them back to Jamaica, where they committed ravages on the unoffending Indians, and made attacks on Columbus and his few but faithful followers. At length, however, the renegades, after suffering some loss in a battle, were permitted to return to their allegiance; and, on the 28th of June 1504, Columbus bade a final adieu to the shores of Jamaica, in vessels prepared for his relief. In 1509, three years after the death of the discoverer, Jamaica became the theatre of rapine, bloodshed, and every species of cruelty. It was placed at the disposal of the two governors of the Darien government, to make what use of it they thought fit, as an emporium whence provisions might be obtained, or a market from which slaves could be taken at pleasure to work in the mines. The rival governors vied with each other in making the most of the island and its unhappy inhabitants. A detail of the enormities committed would sicken humanity. It is sufficient to say, that they were not less aggravated than those perpetrated in other parts of the New World, at a period when crime was uniformly worked on a gigantic scale. The sanguinary reign of the two governors was put a stop to by Diego Columbus, the son of the great navigator, who appeared to assert his prior claim to rule in the island, which the council of the Indies adjudged to be his right. He despatched Don Juan d'Esquimel with seventy men, who formed a settlement at Santa Gloria. The seat of government was fixed on the banks of a small rivulet called Seville Nueva, where a splendid city arose, but of which no memorial now remains except the name. At first it received its designation from the stream on which it stood, but was afterwards called Seville d'Oro. The peaceably-inclined Indians sank unresistingly down to the condition of serfs and slaves to the white superiors, who now usurped the sole occupancy of the soil. The government of Don Juan d'Esquimel appears to have been as mild as it was unfortunately brief. During its continuance, however, the agriculture of the island was materially advanced. The sugar-cane, the vine, and European cattle, were introduced; and from the wool of the cotton tree, which was celebrated in commerce, fabrics were manufactured of a quality so fine as to prove a source of wealth to the Spaniards. But, in their avaricious search for the precious metals, this means of aggrandisement was comparatively neglected. The colony, however, continued to increase rapidly in wealth and importance, and was enabled to send off branches from the parent stock to other parts of the island. But improvement for a time suffered a retardation by the death of Diego Columbus in 1526. He was succeeded by Don Pedro d'Esquimel, who has been singled out from amongst other tyrants as a most uncompromising destroyer of the Indians; and his cruelties, added to those inflicted by French corsairs, called flibustiers, had nearly put a period to the prosperity of Jamaica. The Spaniards fled from these plundering attacks across the mountain range, on the further side of which they founded St Jago de la Vega, which soon rose to be a flourishing city. Meanwhile, the French flibustiers reduced Seville d'Oro to ruins in their attacks upon the Spaniards; for the wars between Henry of France and Charles V. were in part transferred from the Old to the New World. The native Indians, thus placed as it were between two fires, continued to suffer severely; and it is stated that in 1558 they had been entirely extirpated. By the junction of the crowns of Spain and Portugal in 1580, Jamaica came into the possession of the latter, and new energy was infused into the colony by the Portuguese who emigrated thither. The cultivation of sugar and other articles was prosecuted with energy; and the breeds of live stock which had been originally imported from Hispaniola increased so rapidly, that a considerable trade arose in provisions, land, and hides. Passing over two predatory inroads made by the English in 1605 and 1644, we come to the period when the British made a conquest of the island in 1655. By order of Cromwell, a considerable armament was fitted out for the conquest of Hispaniola, at the moment that hostilities were declared against Spain in Europe. The expedition was despatched under the command of General Venables and Admiral Penn; but the intentions of the English were frustrated by the vigilance of the Spaniards. To make amends, however, for the discomfiture, Jamaica was captured in May 1655, after having remained in the possession of Spain for a period of 146 years. For some time little progress was made, many of the Spaniards still retaining possession of the mountains, and causing annoyance to those in the plains. But after some years they were gradually reduced, notwithstanding occasional assistance obtained from Cuba. A more formidable attempt to recover the island was made by the Spaniards in 1658, but without success. Under its first governors, Jamaica became the head-quarters of buccaneers, who infested these seas, and derived untold wealth from the plunder of the Spanish colonies, and vessels laden with the spoils of the New World. A considerable proportion of the population consisted of outlaws, and soldiers and negro slaves likewise began to be imported by the British, whilst emigration from England on a small scale commenced. Charles at his restoration adopted various lenient and wholesome measures to stifle the feuds which existed between the republican and royalist parties, and held out every encouragement to new settlers. In 1662, on the accession of Lord Windsor to the chief authority, a municipal government was constituted, and other means adopted to secure subordination, peace, and justice to all. In 1664, a popular legislative assembly was established, and for sixty-four years it continued to check the encroachments of the crown, as well as to regulate the internal affairs of the island. In about fourteen years after Jamaica came into the possession of Britain, it exhibited a remarkable progress in commercial prosperity. Fifty-seven sugar works, forty-nine indigo works, forty-seven cocoa walks, and several salt pans, attested the enterprise and industry of the colonists. Cattle, sheep, goats, and tame hogs, were reared in great numbers; and attention had been turned to the cultivation of cotton, tobacco, arnotta, and other articles. The white population at this time exceeded 15,000. In 1684, the impolicy of slave labour became apparent, in a serious revolt of the blacks, which, however, was speedily suppressed; but the maroons or runaway negroes became exceedingly troublesome to the planters. Two serious calamities overtook Jamaica within the space of two years. The first was the destruction of Port Royal, by one of those sudden convulsions to which this region of the globe is so liable. With the exception of about two hundred houses of the fort, the whole town, with its vast wealth, was submerged by the overflow of the sea. The greater number of the inhabitants perished, and their dead bodies, floating in shoals in a putrid state about the harbour, occasioned an epidemic, to which three thousand individuals fell victims. This earthquake took place in June 1692; and, exactly two years afterwards, a formidable descent was made on the island by the French; but the militia gallantly repulsed the invaders. During the remaining years of the seventeenth century, no memorable events occurred in the annals of Jamaica. The earlier part of that which followed was marked by various attempts made to bring the supplies raised by the representatives of the people under the control of the crown; but without success. In 1727, the revenue bill passed through the House of Assembly, the required fund being L.8000 per annum; and that which has been termed the magna charta of Jamaica was passed, namely, that the laws and statutes of England, which had been introduced and acted upon, should be considered as part of the legislative code of the island for ever. Matters being thus arranged, the prosperity of the colony continued to increase, notwithstanding the annoyance given to the planters by the negro marauders. In 1760, there took place a desperate revolt of the Indians, which ended in the destruction of the greater number of the rebel slaves. The contest was characterised by acts of cruelty and barbarity, which rivalled the early atrocities of the Spaniards. Some were burned, and others, gibbeted alive, were allowed to be broiled to death by a tropical sun. The slaughter or transportation of about one thousand slaves made little impression upon the population, which rapidly increased. The energies of Jamaica were called forth on the occasion of the meditated attack of the combined fleets of France and Spain in 1782. But the victory gained by Admiral Rodney, on the 12th of April of that year, over the French squadron, preserved the island to the British crown. The Jamaicans showed their gratitude by erecting a handsome marble statue in memory of the hero who triumphed on that day. Along with the other colonies of Great Britain, both in the East and West Indies, Jamaica suffered by the imposition of heavy duties on the produce of the island when imported into England. In 1795, another alarming insurrection of the maroons took place, on account of the intemperate policy of Earl Balcarras, then governor of the island. This rebellion continued upwards of seven months, the war being carried on with savage cruelty on both sides; indeed excesses were committed by the whites, and means employed to subjugate the maroons, which tended more to exasperate than to bring them under control. Into the particulars of this intestine commotion it were superfluous to enter. The savages exhibited their deep hatred of the whites by all those methods of retaliation common to barbarous tribes. Without openly facing the military forces which were sent against them, they lay in covert, and, whenever an opportunity presented itself, surprised them by unexpected sallies. In the fastnesses of the mountains they found a secure retreat; and as the ordinary means of civilized warfare appeared inadequate to bring the contest to a speedy issue, the governor resolved to call to his aid the bloodhounds of Cuba. This bears the aspect of a harsh, but it finally turned out to be a merciful expedient; for it paralyzed the energies of the Indians, and terrified them into a general capitulation. Their lives were spared, but they were transported, at the expense of the island, first to Nova Scotia, and afterwards to Sierra Leone in Africa. The only other slave insurrection which threatened the well-being of the colony, was that which took place in 1831–32; and with this it is hoped that the servile or predial war which the island has so often been doomed to witness will for ever cease. By the slave emancipation bill the principal ground for dissatisfaction on the part of the black population has been removed; but a discussion of this subject, with the results of the measure, belongs to another part of the present work. Besides the destructive visitation already noticed, Jamaica has repeatedly been visited by earthquakes, although only on one occasion was serious injury sustained. The hurricane, that scourge of the western archipelago, has not passed innocuously over this island. One of these, which occurred in 1780, was particularly destructive, the loss of life and property being both very great on that occasion. Besides these evils, the diseases of this country are occasionally malignant; the yellow fever, in particular, has long been proverbially fatal.

Jamaica is somewhat of an oval shape, and its surface is more beautifully diversified by hills and valleys than that of any other island in the West Indies. An elevated ridge, called in the eastern and highest part the Blue Mountains, runs longitudinally from east to west through the centre of the island, and occasionally rises to nearly 8000 feet above the level of the ocean. Other high ridges running from north to south occasionally intersect this chain. On the south they approach to the sea in gigantic spines, difficult of access, and covered with dense forests. On the opposite side the aspect of the country is very different. Instead of being rugged and abrupt, the hills are remarkable rather for their beauty than their boldness. They are of a gentle acclivity, uniformly rounded at the top with singular felicity, and commonly separated from each other by spacious vales and romantic inequalities. This gently-undulating surface is diversified with groves of pimento, luxuriant pastures, and all the exquisite verdure of the tropics. Viewed from a lofty eminence, the country presents an aspect of grandeur united with beauty, which can scarcely be surpassed. A splendid panorama of mountains appears towering up to the clouds, whilst, lower down, vast savannahs or plains clothed with various vegetation, vales, ravines, majestic woods, rivers, cascades, and mountain torrents, appear spread out before the eye of the spectator in all the beautiful irregularity of nature. The view of the island from the sea has also been celebrated by voyagers for its splendour. At Point Morant, the eastern cape of Jamaica, the scenery is magnificent. The Blue Mountains appear embosomed in a stratum of clouds, the rugged hills below being furrowed with ravines, and descending abruptly to the sea.

Upon a nearer approach, they are found to have their sides covered with black forests; whilst patches of bright green, and white houses, are descried on running along the south coast towards Port Royal. From Fort Nugent, which is conspicuous under a steep hill, to Port Royal, there is a narrow bit of land called the Palisades, composed of sand overgrown with mangroves, and studded with grave-stones. Behind this is the harbour of the capital; and Kingston is seen stretching over an extended level, and encircled by the loftiest ridge of the Blue Mountain chain. The heights of the principal mountains have been computed as follows: Blue Mountain Peak, 7770 feet; ridge of the same, 7163 feet; Portland Gap ridge, 6501 feet; Portland Gap, 5640 feet; Catherine's Peak, 4970 feet; with others of a lower elevation. It is stated, however, by some authorities, that the three very remarkable peaks on the grand ridge of the Blue Mountains, called Coldridge, have their respective summits 8184, 7656, and 7576 feet above the level of the sea, whilst other mountains of the same chain exceed a mile in height. The greater number of the mountains present a conical form, with steep but forest-clad declivities, approaching very near the shore on the north coast, and leaving plains of about twelve miles wide on the south. The dark and deep ravines between the lofty mountains, denominated cockpits, are closed in by dense woods, and present a striking contrast to the lower mountains, where coffee, pimento, cotton, capsicums, and other tropical vegetables, flourish luxuriantly.

Jamaica is abundantly supplied with water. Upwards of two hundred rivers have been enumerated; but, owing to the irregularity of the surface of the country, few of these are navigable for vessels of any burden. Black River, the largest and least rapid of these, flows through a level country, and is navigable by small craft for about thirty miles. The other chief rivers on the south side are Rio Cobre and Rio Minho; and on the north Marthabræ, White, Ginger, and Great Rivers. It is a striking fact, that in an island of such limited extent as Jamaica, there are no less than forty rivers varying from twenty to an hundred feet or more in breadth. They are all of great value, turning the mills and irrigating the plantations through which they flow, besides adding a beautiful feature to the landscape. The springs and rivulets are very numerous, but are unequally distributed. In some parts of the island seven or eight may be enumerated within the circuit of as many miles; whilst other districts are so far removed from water, that, for supplying their necessities, the inhabitants are obliged to have recourse to tanks and ponds. Several of the springs possess medicinal virtues. Two of a sulphureous nature, in particular, one hot, and the other cold, are celebrated as exceedingly beneficial in cutaneous diseases. With regard to harbours, the Jamaica shore has sixteen secure havens, besides thirty bays, roads, or shipping stations, which afford good anchorage.

The soil of this island is in most places deep and fertile. On the north side there is a species of red soil, the shades of which vary from a deep chocolate to a rich scarlet, and in some places approach to a bright yellow. What is denominated the brick mould is a deep, warm, yellow, hazel mould, reposing on a retentive under stratum. This is reckoned one of the best soils in the West Indies for the cultivation of sugar-cane. It is of great depth, easily laboured, and so inexhaustible as to require no manure. The black shell mould is the next in fertility, and this it owes to the mineral salts and exuviæ which are intermingled with it. The principal soils on the interior hills and mountains of Jamaica have been thus enumerated: A red clay, on a white marl; a red clay, on a grit; a reddish-brown clay, on marl; a yellowish clay, mixed with common mould; a red grit; a loose conchaceous mould; a black mould, on a clay or other substratum; a loose black vegetable mould, on rock; a fine sand; and the varieties of all the foregoing soils. The mountain land in general, when first cleared of its wood, possesses more or less a deep surface of rich black mould mixed with shells, a soil which will grow anything. Different parts of the island are characterised by peculiarities of soil, which are either those enumerated, or their varieties intermixed with different mineral or earthy substances. Silver and golden mica are frequently met with, and sometimes mistaken for the genuine metal. Amongst other mineral substances found, are mixed and purplish schistus, and the hard lamellated amianthus, which occurs in large detached masses, having all the appearance of petrified wood. White freestone, quartz of different species, and limestone, are abundant. Subcrystalline spar is found in small detached masses, and rock spar in blocks of great magnitude. A species of bastard marble, having a smooth even grain, is frequently used for limestone. There is a species of smooth clammy marl found, which is sometimes eaten by the negroes when they are diseased, to the detriment of their health. Lead ore, rich, and heavily impregnated with silver, striated antimony, varieties of copper ore, and iron-stone, which is attracted by the magnet, are found; but neither gold nor silver ore has yet been discovered, although the natives possessed these metals in abundance when the island was first visited by the Spaniards.

The climate of Jamaica is conformable to the latitude in which it is placed, but the heat is by no means so fearful as is usually represented. The highest temperature of course prevails in the low situations, those more elevated being colder, in conformity with nature's universal law. The climate of the island since its cultivation has undergone very considerable change. The medium heat at Kingston throughout the year is 80°, and the minimum 70°, of Fahrenheit. The latter is the maximum at eight miles from Kingston; and at an elevation of from 4000 to 5000 feet, the average range is from 55° to 65°, the minimum in winter being 44°, of Fahrenheit. The alternation of temperature is from eight to ten degrees on the south side of the mountains, and it is more so on the north; but the transitions are not so sudden and detrimental as in many parts of the continent of North America. The grand compensation for excess of temperature is afforded by the breezes which regularly every morning set in from the sea to the land, and every evening flow from the land towards the sea, as it were by a wise provision of nature, to preserve the equilibrium which the intense heat of the noon-day sun has disturbed. During the most sultry months, also, a succession of light, fleecy clouds continually cross the sun's disc, and thus, by intercepting his rays, mitigate their general ardency. It is cooler and more salubrious on the north side of the island than on the south, and the dwellers on the mountains enjoy a purer and more wholesome air than those resident on the low grounds. There is no striking variation of season, excepting what is occasioned by the alternation of dry and rainy weather. Thunder and lightning are prevalent, without being mischievous; and although the hurricane season ranges from July to October, severe storms at the windward Caribbee Islands are not experienced at Jamaica. The rains do not always take place in the same months; and in different parts of the island there is a considerable variation in the time of their commencement. In the mountains they are earlier, more frequent, and more heavy, than in the low country. In the latter, one district will have rain a month or six weeks sooner or later than another not twenty miles distant from it. What are called the spring rains sometimes do not set in till June, and even later; but occasionally they commence as early as March or April, which is always a great impediment to agricultural operations, this being the time for getting in the sugar crops on the north side of the island. The seasons vary much on either side. On the south, spring may be said to range from November to April, summer from May to August, and winter from September to October. On the north, however, winter ranges from October to March, and on this side there is a more plentiful supply of rain than on the other, but distributed in smaller and more frequent showers. It is, moreover, cooler, and has a vegetation of greater bulk and height. The spring rains are the most violent, and the atmosphere is then exceedingly sultry, and, being much charged with electricity, thunder storms are of frequent occurrence. The distribution of rain is sometimes very capricious, some parts being favoured with plenteous showers, whilst plantations divided from them only by a ridge of hills suffer from drought; and it often happens that, whilst the mountainous regions are visited by daily torrents, the low country is parched for want of rain. During droughts, however, vegetation is much assisted by the fall of dews. The climate of Jamaica is by no means so inimical to the human constitution as is generally represented, that is, provided those resident on the island live temperately. Fevers of various kinds are not uncommon; but the malignant epidemic, the yellow fever, has of late years almost, if not quite, disappeared from Jamaica and the other West India islands. Generally the climate has improved, and the high lands of this beautiful isle are well adapted to the European constitution, and they will be more especially so when they become cleared and cultivated. There are, besides, many districts in the interior where climate and soil are nearly as favourable to health as in any part of Britain; districts which are crown property, and at present lying waste.

Besides the vegetable productions indigenous to Jamaica, the island has been enriched with numerous exotics, the whole forming a vast and interesting catalogue of plants and trees, which our limits will not admit of our enumerating or describing in systematic detail. The forests abound with woods fit for various purposes, as building, mill-work, wheel-making, cabinet-making, dyeing, and so on. There are several species which, from their extreme hardness, cannot be used in cabinet-making, but are valuable for building and other purposes in which durability is principally required. Of these, the black and neesberry bully trees, the green heart, the rose-wood, and fiddle-wood, grow to a great height. The iron-wood, the nature of which tree corresponds with its name, does not grow to a great size, and is principally used for rough posts for the negroes' houses. There are various beautiful woods for ornamental cabinet work, of which the mahogany, the bread-nut-heart, and the satin-wood, are most highly esteemed. The mahogany tree is one of the most elegant in the island, and grows to from forty to fifty feet in height; but having been found a profitable article of exportation, the greater part has been cut down for that purpose, and there are not many trees now remaining on the island. The bread-nut tree is pretty abundant in most parts of Jamaica. Its wood is beautifully variegated, and takes a fine polish. The leaves are a nutritious food for horses and other animals; and the negroes find a substantial article of diet in the kernels of the fruit. The cedar grows to a great size, sometimes measuring thirty feet in girth near the root, and it is of proportionable height. The cotton-tree is the largest of all the trees on the island, but it is only used for making canoes, which are hollowed out from the trunks. The pimento is a highly valuable tree, and it flourishes spontaneously in great abundance on the north side of the island. This tree is celebrated for its beauty, and the leaves, when bruised, emit a fine aromatic odour, nearly as powerful as that of the spice itself. A single tree will produce one hundred and fifty of the raw, or one hundred pounds of the dried fruit. One of the most useful trees in the island is the bamboo, which is applied to numerous important purposes. The trumpet tree, which grows from thirty to forty feet in height, produces an agreeable fruit similar to our strawberry; its strong and fibrous bark is used for cordage, and its light trunk for bark logs, and the like purposes. One of the most curious trees is the mangrove, which takes root in the sands, and grows within the margin of the ocean. The coffee-tree is a handsome plant, and its fecundity is much improved by regular pruning. The coffee-bean is covered with a pulp, which when ripe assumes a fine crimson red. The cocoa-tree grows to the height of from fifteen to twenty feet, and bears its nuts in pods. The cultivation of this article is now neglected, not much more being raised than is necessary for the consumption of the inhabitants. The oil-nut tree (*ricinus*), which produces the castor oil, grows to the height of twelve or fifteen feet, and has a large indented leaf. It bears the fruit, which produces the oil, in clusters. There are two species of the cabbage-tree, the Barbadoes and the native cabbage-tree, the former being the most stately and beautiful. The cocoa-nut tree grows in great luxuriance, and abounds in every part of the island. Besides the above trees, Jamaica is plentifully provided with black and green ebony, yellow sanders, lignum vitæ, fustic, logwood, bitter wood, the valuable palmetto (sometimes one hundred and forty feet in height), and others. There is an abundant supply of the most delicious fruits, every month presenting a fresh collation. Amongst these may be mentioned the pine-apple or anana, orange, shaddock, pomegranate, fig, granedillo, neesberry, cashew-apple, kennip, spadillo, banana, mamee (a wild fruit), star-apple, sweet sop, musk-melon, water-melon, sweet melon, citron, avagato pear, several varieties of the mango, the chirimoya, akee, jack-fruit, bread-fruit, very fine grapes, plantain, plum, tamarind, olive, date, mulberry, as well as other delicious fruits. Amongst vegetables, potatoes, yams, cassava, peas and beans of every variety, artichokes, beet-root, carrots, parsnips, cucumbers, tomatoes, radishes, celery, choco, ochro, Lima bean, Indian kale, calalue, and various salads, flourish in abundance. Both maize and Guinea corn grow in great luxuriance in this island; and rice is capable of being raised in certain situations, but it is not an object of attention. Maize or Indian corn is universally cultivated, and it yields an almost incredible return; on an average, it is said, one thousand fold. Guinea grass, which abounds, is considered as of great importance, as the cattle that supply manure to the sugar plantations are fed by it. The various drugs, dye-stuffs, and spices, are of excellent quality. Aloes, cochineal, spikenard, canella, liquorice root, the castor-oil nut already noticed, vanilla, peppers, arrow-root, ginger, ipecacuanha, scammony, jalap, cassia, euphorbia, senna, and others, attest the fruitfulness and capabilities of the soil and climate.

But it is now time to advert to the grand staple plant of the island, the sugar-cane. The question which has divided inquirers into this subject, namely, whether the sugar-cane was indigenous to the Antilles, does not require to be discussed in this place. It seems certain that at an early period this valuable plant was extensively cultivated by the Spaniards in Jamaica; and in 1671 a writer speaks of the complicated sugar works scattered over the island as resembling towns or villages. There are several varieties of the sugar-cane, viz. the common cane of the island, the Bourbon cane (so called from its being brought last from the island of that name, though originally a native of the Society Islands), the transparent cane, the ribbon cane, the Batavian or purple cane, and the green stripe cane. Those chiefly cultivated are the Bourbon and transparent cane. The ribbon cane is also sometimes planted, on account of its hardy nature, though it yields much less juice than the other two. It is the most beautiful of all the species, being finely variegated with alternate stripes of crimson and pale yellow, whence it takes its name. The Batavian cane is in no estimation, being unproductive, and is only preserved as a variety. An idea of the extent of ground appropriated to the cultivation of the sugar-cane may be obtained from the fact, that for some years the importations into Great Britain have averaged, in hundredweights, 1,400,000, which, rated so low as a guinea per hundredweight, would give nearly one million and a half sterling. It is of very fine quality, and, by the improved systems of culture and manufacture which are coming into operation, there seems little doubt but that both the quantity and quality may yet be more extended. The quantity of rum made from the sugar is likewise very great. The average imports made annually into England may be taken at 3,500,000 gallons, which may be estimated in value at one million sterling. The next grand staple plant of the island is coffee. It was introduced into Jamaica in 1728, from which period the cultivation of it was extended, until about the beginning of this century, when it appears to have reached its maximum. This plant thrives in almost every soil about the mountains of Jamaica, and in the very driest spots has frequently produced abundant crops. The importation into Great Britain averages about 20,000,000 pounds yearly, which, estimated at the low rate of one shilling per pound, is another million sterling. Cotton, indigo, and cocoa, are not now so extensively cultivated as formerly, having given way to the foregoing staples of the island. The attention of the planters has recently been turned to other vegetable productions, particularly to the sun-flower, which, it is said, may be rendered valuable in a pecuniary point of view. Its fecundity in this climate gives it an advantage over corn for the common purposes of food for poultry, and when mixed with corn it constitutes a nutritious food for horses. The seeds also yield an oil, which, in the opinion of some, is preferable to olive oil. With respect to the other vegetable productions of Jamaica, such as flowers and flowering shrubs, there is little to demand particular attention. A few European flowers thrive, and there are a variety of others indigenous to the island, which flourish wild in the woods and mountain recesses. Here, even in winter, may be seen, what is often witnessed in the torrid zone, fruits and blossoms suspended at once from the same bough, the rivalship of Pomona and Flora.

Jamaica, like the rest of the islands appertaining to the new continent, when discovered, contained but few species of animals. Only eight varieties of quadrupeds are enumerated as belonging to it, viz. the agouti, peccari, armadillo, opossum, racoon, musk rat, alco, and monkey. The wild hog, the rat, and the mouse, seem now to be the only wild quadrupeds in the island. The wild hogs, which are larger and more fierce than the common kind, frequent the remote woods, and subsist on the fruits and roots with which these abound. The rats are most destructive animals, and their numbers and ravages are almost inconceivable. The island abounds with the feathered tribes remarkable for the brilliancy of their plumage, but there are only a few of them birds of song. Of these the most remarkable is what is termed the nightingale, a species of mock bird, possessing great variety, compass, and sweetness of tone. There are numerous species of the wild pigeon, and also of the parrot; and a variety of aquatic birds, as ducks, teal, coots, divers, and the like. In October the crane and the white galding (one of the heron family), come over in flocks from the island of Cuba. The plover, snipe, and ortolan, are also migratory. Within the last half century the quail has become a very common bird. But the most valuable of the winged inhabitants of the island is the black vulture or carrion crow, which is very useful in devouring all putrid matter.

The sea around this island, and the rivers by which it is watered, abound in excellent fish. There are also salt ponds, which, if properly attended to, might render the planters in a great measure independent of supplies of salt fish from Europe. The sprat, herring, dolphin, anchovy or silver fish, the flying, sword, sun, parrot, rock, king, and gar fishes, the flounder, sole, eel, bream, snapper, mullet, perch, boneeto, Spanish mackerel, sea-devil (weighing from 100 to 300 pounds), old wife, shark, porpoise, sting ray, thrasher, as well as many others, may be caught in abundance. Sea and land turtle are likewise plentiful, and of good eating. Some of the largest rivers contain alligators, but the chief harm which they usually do is the destroying of the fish, and devouring the poultry and pigs which come in their way. There are three species of snake in Jamaica, the yellow, black, and brown snake, the last being the smallest and least numerous of the three. None of these are venomous in their bite, at least to a serious degree. Several species of the lizard abound here, and scorpions and centipedes are common. There is a very troublesome insect called the cockroach, swarms of which infest every house; but the most annoying of these animals is the mosquito. There are numerous fire-flies, which display their harmless but vivid coruscations during the night. Bees are very numerous in the woods, and the honey which they produce is of an exquisitely fine flavour.

Amongst the animals useful to man, the ox may be placed first. Oxen, though generally smaller than those of England, are capable of performing a great deal of labour; and they are chiefly employed in those operations for which horses are used in Britain. The horses bred in the island are middle sized, hardy, and active, well fitted for the saddle or the harness, but not for the cart or plough, to which they are never yoked. The mules in Jamaica are far more hardy than the horses, and are consequently more valuable to the planter in assisting him in his operations. The sheep are very good, and the mutton is excellent, but high priced. Goats thrive and increase with little care, and the milk they yield is much superior to that of cows. For the most part the foregoing animals feed on the Guinea grass, and occasionally on the leaves of the bread-nut tree. Hogs are very plentiful, and their flesh is sweet and delicious. All kinds of poultry are raised here in great abundance, excepting geese and the common duck. But the Muscovy duck, the turkey, the Guinea fowl, and the common dunghill fowl, thrive and multiply wonderfully well.

Jamaica is divided into three counties, viz. Surrey, Cornwall, and Middlesex; and these are subdivided into twenty-one parishes. Surrey comprises seven parishes, has an area of 1,522,149 acres, and contains two towns and eight villages; Cornwall comprises five parishes, has an area of 1,305,235 acres, and contains three towns and eight villages; and Middlesex comprises nine parishes, has an area of 672,616 acres, and contains one town and thirteen villages. Kingston, the most considerable town in the island, and in reality, though not nominally, the capital, is situated on a gentle slope of about one mile in length, which is bounded on the south by a spacious basin, through which all vessels must advance beneath the commanding guns of Port Royal. The extended inclined plane, on the verge of which Kingston stands, is enclosed on the north by the loftiest ridge of the Blue Mountain chain, termed Liguana, which forms a semicircle, and terminates on the east at the narrow defile of Rock Fort. From this a long neck of land stretches to Port Royal, and forms the south barrier of a beautiful haven. On the west the semicircle terminates at a contracted pass, upon the edge of an impracticable lagoon, from which the main land sweeps round to Port Henderson, which, together with the projecting salt ponds, forms a natural harbour, where all the navies of Europe might anchor at once. The entrance is defended in such a manner as to render it altogether unassailable by sea. For nine miles around Kingston stretches an alluvial plain, surrounded by a series of irregular mountains, some of which have a considerable elevation. Kingston is principally built of wood; and the houses, which are generally two stories in height, have piazzas fitted up all round with Venetian blinds, or "jalousies," as they are termed. The streets, which are long, straight, and regular, incline gradually to the harbour, being intersected at right angles by some cross ones. There are several handsome private buildings in the West India style; the public offices are in some instances elegant; and the English and Scotch churches are spacious structures, particularly the former, which is built on a picturesque spot, commanding a splendid view of the city, the plains around it, the amphitheatre of mountains, and the spacious harbour of Port Royal. There are some good institutions here for charitable purposes, particularly the free school, the hospital, the lunatic asylum, and the asylum for deserted negroes. There are excellent stores for all descriptions of goods, and during crop time the wharfs present a busy spectacle, being crowded with buyers and sellers of all kinds of goods here trafficked in. Kingston contains about 30,000 inhabitants, and lies in longitude 76. 33. west, latitude 18. north. On a plain at the top of the declivity on which Kingston is built, are the fine barracks called Up-Park Camp. The camp covers an irregular square of between two and three hundred acres, sloping towards Kingston. The barracks consist of two long parallel lines of buildings, extending from east to west, two stories high, having a six feet basement, an excellent hospital, and a splendid bath. The whole cantonment is surrounded by a wall six feet in height, and surmounted by an iron palisading. Twelve hundred and eighty-four European soldiers are here comfortably encamped; and the attached offices are spacious, lofty, and commodious. A description of the other military stations may also be introduced here. Port Royal is situated nearly at the extremity of a tongue of land which forms the boundary of the harbours of Kingston and of Port Royal. A great part of the town of Port Royal is only a few feet above the level of the ocean, and the tongue of land towards the sea is frequently inundated. The royal naval yard lies to the north, the naval hospital to the south-west, and the works of Fort Charles and the soldiers' barracks to the southward. The fortifications are very strong, and the situation, though low, is healthy, from its exposure to the sea breeze. The harbour is capable of containing a thousand large ships with convenience. It was upon this spot that the former Port Royal stood when it was overwhelmed by the earthquake in 1692, and, with two thousand houses, was buried eight fathoms under water. On the shore opposite to Port Royal is Apostle's Battery, a small fort erected on a rock. Fort Augusta is a strong fortress, built upon a low neck of land or peninsula, joined to the hills at Port Henderson by a narrow isthmus of sand, having a coal formation for its base. The buildings of the fort occupy the whole area of the point of the peninsula. The barracks are two stories high, well ventilated, healthy, and generally contain four service companies. Stony Hill garrison is situated nine miles north of Kingston, on a ridge of mountains, about 2000 feet above the level of the sea. The barracks, which, generally speaking, are placed on small detached eminences, are capable of containing five hundred men; and as this post commands the grand pass which intersects the island from north to south, it is justly considered as of great importance. Port Antonio, situated at the extremity of the island, eighty miles from Kingston, is nearly insulated. The fort is a half-moon battery, with a magazine in the rear. The barracks are new, elevated, and commodious, but not capable of containing a great force. Marson Town is situated in the interior, between the parishes of Westmoreland and St James, on a very high mountain. The station is excellent, both in a military and a sanatory point of view; and the barracks can accommodate upwards of two hundred men. Lucea, or Fort Charlotte, is built on the north-eastern extremity of a peninsula, being bounded on one side by the bay and harbour of Lucea, and on the other by the sea. Majestic mountains rise immediately behind the town, about one mile from the garrison.

St Iago de la Vega, or Spanish Town as it is usually called, the capital of Jamaica, is situated at the extremity of an extensive plain, extending far to the south, south-east, and west, but with the mountains closely approaching the town on the north and north-west, and distant from the sea at Port Royal harbour six miles. At about a quarter of a mile to the north-east of the city runs the Cobre, a river of considerable depth. The town is small, but the buildings are in the magnificent style of Spanish architecture. The government residence, termed the King's House, is a large building occupying one whole side of a quadrangle. On either side are a variety of public edifices appropriated to government purposes; and the buildings fronting it comprehend the court-house, grand and petty jury, and a variety of other apartments above, whilst the lower part is occupied by a number of public offices. There are many splendid edifices in the town and neighbourhood, possessed for the most part by gentlemen of the legal or medical professions, and in some cases by government officers or country proprietors. Spanish Town has a free school, poor-house, a charity for the support of widows, and another for the support of poor maidens and distressed strangers; and the population amounts to about 5000.

Montego Bay is the chief town and sea-port of St James. It is situated at the foot of a range of mountains, which nearly surround it, except on the sea side, and is, in consequence of its trade, a thriving and pretty populous place. It is not, however, equal to what it once was, having twice suffered severely from fire. There is here a neat church, a school, a jail, and other public buildings, including barracks, which are commodious and comfortable. Falmouth, or Marthabrae, which is fifteen miles east of Montego Bay, is the principal town and sea-port of Trelawny. From being an inconsiderable village, this place has become larger and more populous than Montego Bay. It has derived its advantages from its harbour, where a greater quantity of produce is shipped than from any other part of the island, with the exception of Kingston. There is a good church here, a handsome and spacious court-house, a marine hospital, a neat jail, substantial and commodious barracks, with an hospital, stores, and quarters, and a free school. Savannah-le-Mar is a fine military station, in the midst of a highly-cultivated country. The town is situated on the beach, from which a low alluvial flat extends for several miles. In this plain, about one mile from the town, is an excellent range of barracks. In the other towns there is nothing that claims particular attention; each of them having its church, its court-house, its free school, its jail, and its workhouse.

Jamaica is ruled by a governor or captain-general, aided by a council of twelve, and a house of assembly. The

Jamaica. governor is always, and the council generally, appointed by the king, through his secretary for the colonies, from amongst the *ex officio* justices of the peace. The governor, who bears the title of his excellency, is invested with the chief civil and military authority, and has the disposal of such appointments as his majesty does not reserve to himself or his ministers. The council of twelve are appointed by mandamus from the king, and hold their offices during pleasure. The members of this body stand in the same relation to the governor as the privy council in England does to his majesty, giving advice to the superior when necessary. They also constitute a part of the legislature of the colony, and occasionally sit as judges. The lieutenant-governor, chief-justice, attorney-general, and the bishop, are all *ex officio* members of the council. The assembly consists of forty-five members, each of the parishes sending two representatives, and Spanish Town, Kingston, and Port-Royal, one additional member each. The qualification for a representative is a freehold of L.300 per annum, or a personal estate of L.3000. An elector must be of age, and possessed of a freehold of L.10 per annum in the parish for which he votes. The governor and council may, as occasion requires, summon the assembly together; and the former, of his own authority, can adjourn, prorogue, and dissolve them. They have the sole power of levying taxes, and the distribution thereof, with the exception of an annual permanent revenue to the crown of L.10,000. The council and assembly, with the consent of the king or the governor, may make laws, statutes, and ordinances for the public peace, welfare, and good government of the colony, provided these be not repugnant, but, as near as may be, agreeable, to the laws and statutes of Great Britain. The English common law is in force in Jamaica, but many of the statute laws are not; for example, the game-laws, poor-laws, bankrupt-laws, and most of those relating to the revenue. An English statute, to have force in Jamaica, must be re-enacted by the colonial legislature. With regard to the imposition of any duty payable in the colonies, Jamaica is placed in the same situation as the other colonies of Great Britain. By the 18th Geo. III. cap. 12, the king and parliament declared, that thenceforth they would not impose any duty payable in the colonies, except for the regulation of commerce, the produce whereof should always be applied to the use of the colony in which it is levied. The English bankruptcy laws are not in force here; but there is in force the insolvent debtor's act, by which a debtor, on making oath that he is possessed of no property above bare necessaries, and delivering his books, if he has any, into the hands of the deputy-marshal or sheriff's deputy, is, after remaining three months in jail, exonerated from all demands against him. Any person proposing to leave the island must give three weeks' notice of his intention, on account of creditors.

The supreme court of judicature holds its sittings in Spanish Town, three times a year, for three weeks each time. The chief justice, a nominee of government, presides in it, and with him are associated several assistant-judges, who hold their offices during pleasure. The jurisdiction of the supreme court is co-extensive with those of the courts of king's bench, common pleas, exchequer, and insolvent debtors in England, taken collectively. It also decides on questions relative to trade and navigation, the laying on of duties or customs on the import and export of goods, on informations for land under the quit-rent acts, and all escheats; and is likewise a court of appeal from the inferior courts of common pleas. There are two assize-courts, one for the county of Surrey, and the other for the county of Cornwall. Their sittings are similar to those of the supreme court, but at different periods. For each of these there are eight assistant judges appointed, two or three of whom sit in turns with the chief justice. They receive no salaries, and, like the judges of the supreme court, they hold office only during his majesty's pleasure. The several inferior courts of common pleas have jurisdiction over all causes (except those in which a freehold is concerned) to the value of L.20 with costs; but, by the aid of a *justicias* from the chancellor, who is the governor, they may hold pleas to any amount, except in actions where the title to land or negroes is concerned. These courts are held at the same time, and in the same place of the respective precincts, as the justices of the peace hold the quarter-sessions, once in every three months; but some of them have the privilege of sitting oftener.

The parishes are under the government of a chief magistrate, termed the *custos rotulorum*, and bench of justices, who hold sessions of the peace every month, and courts of common pleas, for trying actions to the extent of L.20; debts not exceeding 40s. being determined by a single justice. Each parish has a rector and church officers, according to the number of churches or chapels therein; the vestries consist of the *custos*, two magistrates, ten vestrymen, and the rector; the vestries have the power of assessing and appropriating local taxes, alloting labourers for repairing the highways, appointing way-wardens, nominating collectors of public and parochial rates, and regulating the police of their several parishes.

In the court of chancery the governor sits as chancellor, with powers similar to those of the lord high chancellor in England, and the proceedings are the same as those of the English court of chancery. There is also a court of error, where appeals lie from the courts of law, and of which the governor and council are the judges; a court of ordinary, for determining ecclesiastical matters, of which the governor is judge; and a court of vice-admiralty, the judge of which is appointed by the crown.

The commerce of this important island consists of the trade with the mother country, the trade with British North America, and the trade with the island of Cuba and other Spanish islands, the Spanish Main, and other territories on the American continent formerly belonging to Spain. Its extent will be seen by the following return.

	Shipping Inwards.								Shipping Outwards.							
	From Great Britain.		From British Colonies.		From Foreign States.		Total Inwards.		To Great Britain.		To British Colonies.		To Foreign States.		Total Outwards.

Jamaica.

It is always a difficult matter to form a definite idea of the amount of property in any place; but that in Jamaica, moveable and immoveable, is not over-estimated at L.50,000,000 sterling money.

The annual income, or ways and means, of the island, on an average of ten years, has been estimated at about L.490,000. The returns, however, are far from being explicit, for it is nearly impossible to ascertain the actual state of taxes in the island, and the nature of their bearing and operation on commerce. The expenditure for 1831, according to a return laid before parliament, amounted to L.370,000, the items being as follows:—

Governor	L.5,500
Chief justice	4,000
Assistant judges	3,400
Speaker of assembly	1,400
Governor's secretary	3,000
Officers of his majesty's customs	23,390
Clergy of established church	23,593
Ditto Presbyterian	1,201
Ditto Roman Catholic	200
Charitable institutions	14,656
Army expenses	157,032
Clerk of supreme court and provost marshal	1,160
Secretary of commissioners of public accounts	1,000
Secretary of ditto correspondents	300
Clerk of board of works	400
Commissioners of stamps	1,550
Deputy receiver-general and secretary at the outports	1,560
Marshals of militia regiments	1,050
Alien and bonding office	600
Island agent	2,542
Captains of forts	669
Officers of assembly	6,146
Island botanist	560
Engineer and surveyor of public works	740
Storekeeper	500
Receiver general	7,000
Law expenses and jails	14,874
Roads, bridges, and public buildings	25,850
Printing	7,159
Militia arms, and gunpowder	8,594
Board of works	8,890
Premium on increase slaves	8,120
Registry and vestry returns	5,378
Maroons, and superintendent of maroon towns	2,030
Miscellaneous	10,000
Interest on public loans	16,900
	L.370,000

According to the Jamaica budget for 1832, the income of the island was as follows:—Taxes and internal duties, L.207,367; duties on vessels and cargoes, L.95,970; certificates in circulation, L.399,205; and loan certificates, including L.64,415 loan deposits, L.250,035. Of the expenditure, the military amounts to L.184,143, besides L.222,729 for the general defence of the island, of which L.176,691 was incurred for martial law in 1832. The civil expenditure was L.85,078, of which L.15,544 was for interest. "On a general view," says Montgomery Martin, "it may be stated that the annual public revenue of Jamaica is L.300,000; and the vestry or parish, or local taxation of the different counties, a nearly similar sum." Jamaica thus contributes a very considerable sum to the national exchequer.

The want of an established currency in the West India islands has long been felt as an evil. In no two islands is the currency alike; and in these again it varies in proportion to sterling money, thus:

	Sterling.		Currency.	Dollar.		Currency.
Jamaica	L.100	=	L.140	1	=	6s. 8d.
Barbadoes	100	=	135	1	=	6s. 3d.
Windward isles, except Barbadoes	100	=	175	1	=	8s. 3d.
Leeward isles	100	=	200	1	=	9s.

The metallic currency of the island is estimated at L.100,000. The paper currency consists entirely of the island checks issued by the receiver-general, under the orders of the board of accounts, and upon the security of the island and its revenue. The coins in circulation in this island are chiefly Spanish. There are also some Portuguese gold pieces, and guineas and sovereigns. The Spanish gold coins are doubloons, value sixteen dollars; half doubloons, pistoles, value four dollars; and half pistoles.

In time of war the naval establishment of Jamaica is considerable, but the peace establishment consists only of a few vessels. The military establishment of the island generally includes the head-quarters of four European regiments of the line, one West India regiment composed of Caffres or West Coast African negroes, and a strong detachment of artillery, making altogether an army of about 3000 men; and of colonial militia from 16,000 to 18,000 men at arms, infantry and cavalry, distributed throughout the several counties. All white males from the age of fifteen to sixty are obliged by law to provide themselves with suitable clothing, and to enlist in either the cavalry or militia. Substitutes are not allowed.

The general post-office and packets next claim our attention. This department comprises a deputy postmaster-general, a principal, and numerous other clerks, in Kingston, and deputy-postmasters stationed at proper and convenient distances along the post-roads in every direction. Mails for all parts of the island are despatched every Saturday evening, and an extra one for Spanish Town every Friday morning. Two packets are despatched monthly from Great Britain for this island. The first touches at the Windward Islands, and arrives at Jamaica about the 20th of every month. The second takes a more direct route, and arrives at her destination about a week after the former.

The press, education, and religion, being intimately blended with one another, may be connected together. The press is unshackled by stamp-duties, and on the increase. There are two daily and four weekly newspapers in the island, all conducted with considerable talent, and with little display of party feeling or faction. Education is rapidly spreading under the aid of the local government, as well as by private means. In the budget of the island there is nearly L.10,000 allotted for free schools. The Jamaica free school at Walton Penn, in the parish of St Ann, has L.1620; Woolmer's free school, in the parish of Kingston, has L.1500; Vere free school, L.1120; the Titchfield free school about a similar sum, and so on. There may be about thirty public or free schools, attended by nearly 4000 scholars. Besides these, there are a number of most respectable schools, where classical as well as ordinary education may be obtained. Great efforts have been made for the extension of religion, but whether with a success commensurate to the exertions bestowed it is difficult to say. The outlay by the colonial government for 1831 was nearly L.25,000, of which the curates' stipends amounted to L.8000; rectors' ditto, to L.11,718; expenses of building of chapels, L.1400; annuities of widows and orphans of the clergy, L.2000; salaries of the registrar and appositar of the diocese, L.475; Presbyterian institutions, Jamblicus. L.301; support of kirk in Kingston, L.700; Presbyterian charity schools, L.200. The bishop of Jamaica, whose see extends over the Bahamas and Honduras, has L.4000, and the archdeacon L.2000, per annum. There are fifty-seven clergymen of the established church, twenty-one of whom are rectors; four of the Scotch Presbyterian church, twenty-four of the Wesleyan Methodist persuasion, sixteen of the Baptist, and eight of the Moravian. The crown livings are now in the gift of the bishop. The established clergy are paid partly by stipend and partly by fees. With regard to the expenditure of Jamaica for her ecclesiastical establishments, the Rev. Mr Bridges informs us, that of late years it has not fallen far short of L.30,000 annually. Pluralities are not permitted; and the negro apprentices, as they are now called, are entitled to demand the gratuitous services of the clergy.

Owing to some mistaken feelings, the census of Jamaica has not been taken, so that it is impossible to state with accuracy the actual population of the island. By some it is said to be half a million, which would give seventy-eight persons to the square mile. The following is a summary for 1833, of the returns of the number of slaves, now apprentices, in the island, the number of stock or horned cattle, and the quantity of land in cultivation and pasture. The returns are given in upon oath.

	Slaves.	Stock.	Acres of Land.
Middlesex	121,194	65,416	1,026,486
Surrey	74,286	16,455	390,386
Cornwall	107,152	83,373	818,852
	302,632	165,244	2,235,724

By some the number of whites is estimated at 35,000; and of maroons there are about 1200 in Jamaica. The number of what are denominated free people of colour has not been ascertained, but the total population of the island is not over-estimated at between 400,000 and 500,000.

Before concluding the account of Jamaica, it is necessary to refer to a dependency called the Cayman Isles. These are three small isles, in latitude 19. 20. north, and from thirty to forty leagues north-north-west from Point Negrill, to the westward of Jamaica, the Grand Cayman being the most remote. Cayman-braque, and Little Cayman, lie within five miles of each other, and about thirty-four miles north from the Grand Cayman. These islands were discovered by Columbus, but they were never permanently settled until after the conquest of Jamaica by Great Britain. Grand Cayman, the only one of them occupied, is about one mile and a half long, one mile broad, and contains about 1000 acres. It is very low, but towards the middle of the island vegetation is abundant. These islands are favourite breeding places for turtles, immense shoals of which animals cross the ocean from the Bay of Honduras, to deposit their eggs on the low, sandy shore of the Caymans. The present race of inhabitants, of whose numbers accurate accounts have not been given, are said to be descended from the English Buccaneers, and, from being inured to the sea, form excellent pilots and seamen. The bishop of Jamaica estimated their numbers in 1827 at 1600. They are very healthy, and attain to a great age. Justices of the peace are sent from Jamaica, but in no way are the inhabitants interfered with by the chief settlement to which they belong. They have a chief or government officer of their own choosing, and they frame their own regulations.

With regard to the working of the emancipation bill, by which, from the 1st of August 1834, the slaves aged six and upwards became apprenticed labourers, without any formal indentures, nothing as yet can be said with certainty. Any disturbances which have broken out were anticipated, even by those who were most sanguine as to the success of the measure; but when the negroes shall have become familiar with their change of condition, their transition from a state of slavery to that of freedom, every thing will probably go on prosperously. At all events, from the accounts received, we are entitled to indulge in a less gloomy augury for the future, than has been but too generally entertained by those who investigated the subject, or were interested in the change. (R. R. R.)

JAMBLICUS, the name of two celebrated Platonic philosophers, one of whom was a native of Chalcis, and the other of Apamea in Syria. The first, whom Julian compares to Plato, was the disciple of Anatolius and Porphyry, and died under the reign of the Emperor Constantine. The second also enjoyed great reputation. Julian wrote several letters to him; and it is said he was poisoned under the reign of Valens. It is not known to which of the two we ought to attribute the works which have reached us in Greek under the name of Jamblicus. These are, 1. Protrepticus, seu adhortatio ad philosophiam, Leipsig, 1813, in 8vo; 2. De Vita Pythagoræ, Amsterdam, 1707, in 4to, Greek and Latin, with the corrections and notes of Ludolf Kuster; 3. In Nicomachi Geraseni Arithmeticam Introductionem et De Fato liber, nunc primum editus Græce, in Latinum Sermonem conversus, notis illustratus a Sam. Tennulio, Arnheim, 1688, in 4to; 4. De Mysteriis Ægyptiorum, Venet. Aldus, 1497, in folio, a work filled with theurgic and extravagant notions. Hebenstreit has published a learned dissertation *De Jamblichi philosophi Syri doctrina, Christinæ religioni quam imitari studet, noxia*, Leipsig, 1764, in 4to. The system of the Neo-Platonists was built on the doctrine of *emanation*, according to which all beings are destined, after undergoing several degrees of purification, to return to the Deity, whence they emanated. By this system, the sage may, even in this life, attain to the *intuition* of the divinity, the most sublime end or aim of philosophy. This school admitted the existence of a class of demons, or spirits of an inferior order, mediators between God and man. To enter into communication with them required great purity of manners, and a holiness which disengaged man from every thing terrestrial. Fallen souls inhabit bodies which serve as their prison; and if, during their lives, they have not laboured to divest themselves of their vices, they are, after death, sent back to other bodies still more vile, until they be entirely purified; a doctrine which approximates closely to metempsychosis. The Neo-Platonists also admitted a species of trinity; the soul, according to them, emanated from the intelligence, or second divine essence (νους), which again emanates from the infinite and perfect being. In order to oppose the progress of Christianity, which began to ruin all established religions, it was believed necessary to envelope in obscurity this doctrine of emanations; and hence they affected to regard as the authors of this system Zoroaster in Persia, Orpheus in Thrace, and Hermes in Egypt. (Schoell, *Hist. Abrég. de la Littér. Grecque*, tom. i. p. 203.)

James, St. JAMES, St, called the *Greater*, the son of Zebedee, and the brother of John the Evangelist, was born at Bethsaida in Galilee. He was called to be an apostle, together with St John, as they were mending their nets with their father Zebedee, who was a fisherman; when Christ gave each of them the name of Boanerges, or Son of Thunder. They then followed Christ, were witnesses, with St Peter, of the transfiguration on Mount Tabor, and accompanied our Lord in the garden of olives. It is believed that St

James first preached the gospel to the dispersed Jews; and afterwards returned to Judæa, where he preached at Jerusalem, when the Jews raised up against him Herod Agrippa, who put him to a cruel death, about the year 44. Thus St James was the first of the apostles who suffered martyrdom. St Clement of Alexandria relates, that his accuser was so struck with his constancy, that he became converted, and suffered with him.

James, *St*, called the *Less*, an apostle, the brother of Jude, and the son of Cleophas, and Mary the sister of the mother of our Lord, is called in Scripture the *Just*, and the brother of Jesus, who appeared to him in particular after his resurrection. He was the first bishop of Jerusalem, when Annanias II. high priest of the Jews, caused him to be condemned and delivered into the hands of the people and the Pharisees, who threw him down from the steps of the temple, when a fuller dashed out his brains with a club, about the year 62. His life was so holy, that Josephus considers the ruin of Jerusalem as a punishment inflicted on that city for his death. He was the author of the epistle which bears his name.

St James of the Sword (*San Jago del Espada*), a military order in Spain, instituted in 1170, under the reign of Ferdinand II. king of Leon and Gallicia. Its object was to put a stop to the incursions of the Moors, these knights obliging themselves by a vow to secure the roads. An union was proposed and agreed to in 1170, between these and the canons of St Eloy; and the order was confirmed by the pope in 1175. The highest dignity in that order is that of grand-master, which has been united to the crown of Spain. The knights were obliged to give proof of their descent from families that had been noble for four generations on both sides; they also were required to make it appear that their ancestors were neither Jews, Saracens, nor heretics, nor had ever been called in question by the inquisition.

James, the name of several kings of Scotland and of Great Britain.

James I. king of Scotland in 1423, the first of the house of Stuart, was not only the most learned king, but one of the most learned men, of the age in which he flourished. This ingenious and amiable prince fell into the hands of the enemies of his country in his tender youth, when he was flying from the snares of his unnatural and ambitious uncle, who governed his dominions, and was suspected of designs against his life. Having secretly embarked for France, the ship was taken by an English privateer off Flamborough Head; and the prince and his attendants were confined in a neighbouring castle until they were sent to London. The prince was conducted to the Tower immediately after he was seized, on the 14th of April 1405 (in the thirteenth year of his age), and there kept a close prisoner till the 10th of June 1407, when he was removed to the castle of Nottingham, from which he was brought back to the Tower on the 1st of March 1414, and there confined till the 3d of August in the same year, when he was conveyed to the castle of Windsor, where he was detained till the summer of 1417, when Henry V., for political reasons, carried him with him into France in his second expedition. In this melancholy situation, so unsuitable to his age and rank, books were his chief companions, and study his greatest pleasure. That he wrote as well as read much we have his own testimony, and that of all our historians who lived near his time. Bowmaker, the continuator of Fordun, who was his contemporary, and personally acquainted with him, spends ten chapters in his praise, and in lamentations for his death; and, amongst other things, states that his knowledge of the Scriptures, of law, and philosophy, was incredible. Hector Boyce tells us that Henry IV. and Henry V. furnished their royal prisoner with the best teachers in all the arts and sciences; that, by their assistance, he made great proficiency in every part of learning and the fine arts; and that he became a perfect master in grammar, rhetoric, poetry, music, and all the secrets of natural philosophy, and was inferior to none in divinity and law. This prince's skill in music was remarkable. Walter Bower, abbot of Inchcolm, who was intimately acquainted with him, assures us that he played on eight different instruments, which he names, and especially on the harp, with such exquisite skill, that he seemed to be inspired.[1] Above a century after his death he was celebrated in Italy as the inventor of a new and pleasing kind of melody, which had been admired and imitated in that country. This appears from the following testimony of Tassoni, a writer who was well informed, and of undoubted credit. "We may reckon amongst us moderns, James king of Scotland, who not only composed many sacred pieces of vocal music, but also of himself invented a new kind of music, plaintive and melancholy, different from all other; in which he had been imitated by Carlo Gesualdo, prince of Venosa, who, in our age, has improved music with new and admirable inventions."[2] After spending almost twenty years in captivity, and encountering many difficulties on his return into his native kingdom, he was murdered by barbarous assassins in the prime of life. Many of the productions of his pen have perished, for only three poems that have been ascribed to him are now extant, viz. Christ's Kirk on the Green; Peebles at the Play; and the King's Quair. But slender as these remains are, they afford sufficient evidence that the genius of this royal poet was not inferior to that of any of his contemporaries, and that it was equally fitted for the gayest or the gravest strains. (See *Poetical Remains of James I.* Edinburgh, 1783; and Warton's *History of Poetry*, vol. ii. p. 12.)

James V. king of Scotland, was but eighteen months old when his father fell in the battle of Flodden Field in 1513. When of age he assisted Francis I. king of France against the Emperor Charles V.; a service for which, in 1535, Francis gave him his eldest daughter in marriage. This princess died in two years; and James married Mary of Lorraine, daughter of Claude duke of Guise, and widow of Louis d'Orleans, by whom he had only one child, Mary queen of Scots, born only eight days before his death, which happened on the 13th of December 1542, in the thirty-fifth year of his age. This was the first prince of his family who died a natural death since its elevation to the throne. He is said to have been the author of a humorous composition called the *Gaberlunzie Man*.

James VI. king of Scotland in 1567, and of England in 1603, was son of Mary queen of Scots, whom he succeeded in Scotland, as he did Elizabeth in England. He valued himself much upon his polemical writings, and was so fond of theological disputations, that, to keep them alive, he founded Chelsea College for the express purpose of attaining this object; but it was converted to a much better use by Charles II. His *Basilicon Doron*, his Commentary on the Revelation, his writings against Bellarmine, and his *Dæmonologia*, or doctrine of witchcraft, are sufficiently known. A collection of his writings and speeches was published in one folio volume. He died in 1625, in the fifty-ninth year of his age and twenty-third of his reign.

James, *Thomas*, a learned English critic and divine, was born at Newport, in the Isle of Wight, about the year 1571. Having completed his preliminary studies at West-

[2] Alessandro Tassoni *Pensieri Diversi*, lib. x.

minster School, he entered New College, Oxford, of which he became a fellow in 1593; took his degree as master of arts in 1599; and having collated several manuscripts of the *Philobiblion* of Richard of Durham, which he published in 4to, dedicated to Sir Thomas Bodley, he recommended himself to the favour of that munificent patron of learning, and through his influence was in 1602 appointed keeper of the public library, an office which he held during eighteen years. In 1614 he was created doctor in divinity, promoted to the archdeaconry of Wells, and about the same time presented to the rectory of Mongeham in Kent, not to mention other spiritual preferments. In 1620 he resigned his situation as librarian, and applied himself chiefly to the readings of old manuscripts, in which he assures Archbishop Usher that he had restored three hundred citations, or rescued them from corruptions. Having been chosen a member of the convocation held with the parliament at Oxford in 1625, he there moved to have commissioners appointed to collate the manuscripts of the fathers in all the libraries of England, with the Roman Catholic editions; but as this project did not meet with the desired encouragement, he himself undertook the arduous task, and continued to prosecute it until his death, which took place in August 1629. He left behind him a great number of learned works, the principal of which are, 1. Philobiblion Ricardi Dunelmensis, 1599; 2. Cyprianus Redivivus, London, 1600; 3. Catalogus Librorum in Bibliotheca Bodleiana, Oxford, 1605, in 4to; 4. Concordantiæ SS. Patrum, Oxford, 1607, in 4to; 5. Apology for John Wickliffe, Oxford, 1608, in 4to; 6. Specimen Corruptelarum Pontificiorum in Cypriano, Ambrosio, Gregorio Magno, &c. London, 1626; 7. Index librorum prohibitorum a pontificibus, Oxford, 1627, in 8vo; and, 8, some pieces in manuscript. (A.)

James, *Dr Robert*, an English physician, particularly distinguished by the preparation of a fever powder, was born at Kinverston, in Staffordshire, in 1703; his father was a major in the army, his mother a sister of Sir Robert Clarke. He was of St John's College in Oxford, where he took the degree of bachelor of arts; and afterwards practised physic at Sheffield, Lichfield, and Birmingham successively. He then removed to London, and became a licentiate in the college of physicians; but in what year is not known. At London he applied himself to writing, as well as practising physic; and in 1743 published a Medical Dictionary, in three vols. folio. Soon afterwards he published an English translation, with a supplement by himself, of *Ramazzini de morbis artificum;* to which he also prefixed a piece of Frederic Hoffman upon Endemical Distempers, 8vo. He also published, in 1746, The Practice of Physic, 2 vols. 8vo; in 1760, On Canine Madness, 8vo; in 1764, A Dispensatory, 8vo. In June 1755, when the king was at Cambridge, James was admitted by mandamus to the doctorship of physic. In 1788 were published, A Dissertation upon Fevers, and A Vindication of the Fever Powder, 8vo; with A Short Treatise on the Disorders of Children. This was the eighth edition of the Dissertation, the first of which had been printed in 1751; and the purpose of it was to set forth the success of this powder, as well as to describe more particularly the manner of administering it. The Vindication was posthumous and unfinished; for he died in March 1776, whilst he was employed upon it.

James, *St*, a town of the arrondissement of Avranches, in the department of the Channel, or, as it is sometimes called, of La Manche, in France. It is situated on the river Beuvron, and has a castle, 406 houses, and 2696 inhabitants.

JAMESON, George, an eminent artist, the Vandyck of Scotland, was the son of Andrew Jameson, an architect, and born at Aberdeen in 1586. He studied under Rubens at Antwerp; and, after his return, applied with indefatigable industry to portraits in oil, though he sometimes practised in miniature, and also in history and landscape. His largest portraits were generally somewhat less than life. His earliest works are chiefly on boards, but he afterwards painted on a fine linen cloth, smoothly primed with a proper tone, to help the harmony of his shadows. His excellence is said to consist in delicacy and softness, with a clear and beautiful colouring; his shades are not charged, but helped by varnish, with little appearance of the pencil. When King Charles I. visited Scotland in 1633, the magistrates of Edinburgh, knowing his majesty's taste, employed Jameson to make drawings of the Scottish monarchs, with which the king was so pleased, that he sat to him for a full-length picture, and rewarded him with a diamond ring from his own finger. Jameson always drew himself with his hat on, either in imitation of his master Rubens, or from having been indulged in that liberty by the king when his majesty sat to him. Some of Jameson's works are in the colleges of Aberdeen; and the Sibyls there he is said to have drawn from living beauties in that city. But the greatest collection is that at Taymouth, the seat of the Marquis of Breadalbane; Sir John Campbell of Glenorchy, ancestor of the noble marquis, having been the chief patron of Jameson, who, in fact, attended him in his travels. This artist died at Edinburgh, and was interred in the Greyfriars church-yard, but without a monument. Jameson was but little known in England, and has not been noticed by any English writer on the fine arts, except Lord Orford. But he was much esteemed in his own country; and Arthur Johnston, the poet, addressed to him an elegant Latin epigram on his portrait of the Marchioness of Huntley.

JAMPOL, a town of the province of Podolia, in Russia, the capital of a circle of the same name, and situated on the river Dnieper. It is the frontier town towards the Turkish dominions, and has a quarantine and custom-house. Long. 28. 24. E. Lat. 48. 15. N.

JAMTLAND, a province in the north of Sweden, extending over 17,732 square miles, and bounded on the west by Norway, and on the other sides by Swedish provinces. It is mountainous, as there are five chains of alpine elevations that cross it from west to east, several of whose points are 7000 feet in height. Through some of these ranges routes have been opened, which are still passed with difficulty, from their steepness and ruggedness. Between the ranges are some valleys, which would be fruitful but for the severity of the climate, which is an impediment to the growth of any corn besides oats, with which the inhabitants often mix the bark of the pine-trees to make their bread. The chief nourishment of the inhabitants is supplied by the dairy and the fisheries, but chiefly by the latter. The province yields abundance of timber, and some supplies of copper, lead, iron, and alum. It has but two towns, both small; Ostersund is the capital, with only 200 inhabitants. The whole population is about 32,000 persons. It is between latitude 61. 39. and 65. 6. north.

JAMYN, Amadis, a French poet of the sixteenth century, was born at Chaource, in Champagne, about the year 1540. His parents, who were respectable, neglected no means calculated to promote his education. He received instructions from Dorat, Turnebus, and other learned men, who early inspired him with a taste for letters; and he also studied philosophy and the mathematics with some success; but an invincible predilection led him to poetry, in the cultivation of which he appears to have received marked encouragement from Ronsard, who was then regarded as the greatest man in France. From a passage in one of his elegies, it has been conjectured that in his youth he travelled through part of Greece and of Asia Minor; it is more certain that he visited Dauphiné, Provence, and Poitou, since he cites the names of the cities where he had sojourned, and complains of the reception which he had met with at Poitiers. Ronsard procured him the situation of secretary and reader to the king, Charles IX.; but after the death of his benefactor, he quitted the court, and retired to his native city, where he died about the year 1585, at comparatively an early age. The *Œuvres Poétiques* of Jamyn were published at Paris in 1575, and again in 1577, in 4to. This collection is divided into five books, the first of which contains the pieces addressed to Charles IX. and the great lords of the court, and the four following, sonnets, eclogues, elegies, and other amatory pieces. Jamyn completed, in Alexandrine verses, the translation of the Iliad of Homer, which Hugues de Salel had commenced in decasyllabic measure, and which stopped at the twelfth book; and he had also the merit of perceiving that Homer could only be translated into stately and majestic verses. After having given a first edition of the thirteen last books of the Iliad (Paris, 1574, in 4to), he revised and corrected the work of Salel, which he published along with his own (Paris, 1580 and 1584); and this addition is augmented by a translation of the first three books of the Odyssey. In these translations by Jamyn, there are beautiful verses, and passages rendered in a manner truly poetical; but he has thrown ridicule on his own performance by assigning modern titles to the heroes of the Iliad, and thus giving it the air and appearance of a travesty. (A.)

JANEIRO. See Rio Janeiro.

JANICULUM, a hill on the opposite side of the river Tiber from Rome, said to have derived its name from the city built on its summit by Janus. (Virgil, *Æn.* viii. 354.) At the foot Numa was buried, and many centuries afterwards his tomb is said to have been found here. (Liv. xl. 29.) This part of Rome was at first peopled by the inhabitants of certain Latin cities transferred thither by Ancus Martius. (i. 33.)

JANIZARIES, or Janissaries, an irregular infantry, which, until the year 1826, formed the principal strength of the Turkish army. Vossius derives the word from *genizers*, which in the Turkish language signifies *novi homines* or *milites*. But D'Herbelot tells us that *jenitcheri* signifies a *new band* or *troop*, and that the name was first given by Amurath I. called the Conqueror, who, having selected one fifth of the Christian prisoners whom he had taken from the Greeks, and instructed them in the discipline of war and the doctrines of Islamism, sent them to Hagi Bektasche, a person whose pretended piety rendered him extremely revered amongst the Turks, that he might confer his blessing on them, and at the same time give them some mark to distinguish them from the rest of the troops. Bektasche, after blessing them in his manner, cut off one of the sleeves of the fur gown which he had on, and put it on the head of the leader of this new militia; and from that time, namely, the year 1361, they retained the name of *jenitcheri*, and the fur cap.

At the time when the janissaries were thus instituted, there was not a single power in Europe which maintained a regular body of troops in its pay. The Christian armies were raised at the will of the nobility, who brooked no superior, and seized the first pretext to leave the armies of their sovereign, and return with their vassals to their strongholds. The advantage of union against a common enemy was not felt or appreciated; and victory declared in favour of those troops who to courage and enthusiasm united some degree of discipline, and a blind obedience to the will of their leaders. Such were the janissaries originally. They swept all before them; and, whilst the capture of Christians furnished slaves to supply the vacancies in their ranks, fortune smiled on their prowess and daring. But when this body ceased to form a class separate from the nation; when they were allowed to marry and enrol their children, and the *odas* (companies or regiments) were encumbered with men who preferred an inglorious life in the retirement of their families to the fatigues and dangers of the field; then the janissaries ceased to be formidable to their enemies, and, like the prætorian guards of Rome, were only dreaded by the sultans. Yet on this class did the Porte, until recently, depend for defence against its enemies; and although their inefficiency became daily more apparent, no reform could be effected in the system. In vain did Selim attempt to remodel them; his life paid the forfeit of his temerity. In vain did Mahmoud, upon his accession to the throne, wish to enforce the regulations of Suleiman the Magnificent. The consequence was an insurrection, which, during three days, inundated his capital with blood, and obliged him, in self-defence, to command the execution of his own brother. But the stern disposition of Mahmoud was in no degree daunted by this failure. He now saw that nothing less than the entire destruction of the janissaries would enable him to improve the condition of his empire; and he waited patiently until he could strike a blow with the certainty of success. In 1826, the janissaries again mutinied; but this time they found the sultan prepared, and they gave but the signal for their own destruction. The artillery-men and other troops faithful to the sultan surrounded them in the Etmeidan. They attempted to defend themselves, but without success, and about twenty thousand perished in the hopeless conflict. The suppression of this body, which immediately followed, left Mahmoud at liberty to remodel his army in such a manner as appeared best suited to the times; and, accordingly, he lost no time in taking measures to supply the void occasioned by the destruction of the only military force in the empire. See Turkey.

JANSEN, Cornelius, bishop of Ypres, one of the most learned divines of the seventeenth century, and principal of the sect called from his name *Jansenists*. He was born in Holland, of Catholic parents, and studied at Louvain. Being sent into Spain to transact some business of consequence relating to the university, the Catholic king, viewing with a jealous eye the intriguing policy of France, engaged him to write a book to expose the French as doubtful Catholics, since they made no scruple of forming alliances with Protestant states. Jansen performed this task in his *Mars Gallicus*, and was rewarded with a mitre, being promoted to the see of Ypres in 1635. Before this he had maintained a controversy against the Protestants, upon the points of grace and predestination; but his *Augustinus* was the principal labour of his life, upon which, it is said, he spent above twenty years.

JANSENISTS, a sect of Roman Catholics in France, who followed the opinions of Jansen or Jansenius in relation to grace and predestination.

In the year 1640, the universities of Louvain and Douay, and particularly Father Molina and Father Leonard Celsus, thought fit to condemn the opinions of the Jesuits on grace and free will. This having set the controversy on foot, Jansenius opposed to the doctrines of the Jesuits the sentiments of St Augustin, and wrote a treatise on grace, which he entitled *Augustinus*. This treatise was attacked by the Jesuits, who accused Jansenius of maintaining dangerous and heretical opinions, and afterwards, in 1642, obtained of Pope Urban VIII. a formal condemnation of the treatise; but the partisans of Jansenius gave out that this bull was spurious, or, in other words, composed by a person entirely devoted to the Jesuits. After the death of Urban VIII. the affair of Jansenism began to be more warmly controverted, and gave birth to an infinite number of polemical writings concerning grace. And what occasioned no little mirth was the titles which each party gave to their writings; one writer published *The Torch of St Augustin*, another found *Snuffers for St Augustin's Torch*, and Father Vernon formed *A Gag for the Jansenists*. In the year 1650, sixty-eight bishops of France subscribed a letter to Pope Innocent X. to obtain an inquiry into, and condemnation of, the following propositions, extracted from Jansenius's *Augustinus:* 1. Some of God's commandments are impossible to be observed by the righteous, even though they endeavour with all their power to accomplish them. 2. In the state of corrupted nature, we are incapable of resisting inward grace. 3. Merit and demerit, in a state of corrupted nature, do not depend on a liberty which excludes necessity, but on a liberty which excludes constraint. 4. The Semi-Pelagians admitted the necessity of an inward preventing grace for the performance of each particular act, even for the beginning of faith; but they were heretics in maintaining that this grace was of such a nature that the will of man was able either to resist or obey it. 5. It is Semi-Pelagianism to say that Jesus Christ died or shed his blood for all mankind in general.

In the year 1652, the Pope appointed a congregation for examining into the dispute in relation to grace. In this congregation Jansenius was condemned; and the bull of condemnation, published in May 1653, filled all the pulpits in Paris with violent outcries and alarms against the heresy of the Jansenists. In the year 1656, Pope Alexander VII. issued another bull, in which he condemned the five propositions of Jansenius. However, the Jansenists affirm that these propositions are not to be found in his book; but that some of his enemies, having caused them to be printed on a sheet, inserted them in the book, and thereby deceived the pope. At last Clement XI. put an end to the dispute by his constitution of the 17th July 1705, in which, after having recited the constitutions of his predecessors in relation to this affair, he declares, "That in order to pay a proper obedience to the papal constitutions concerning the present question, it is necessary to receive them with a respectful silence." The clergy of Paris, in the same year, approved and accepted of this bull, and none dared to oppose it. This is the famous bull *Unigenitus*, so denominated from its beginning with the words *Unigenitus Dei Filius*.

JANSSEN, Cornelius, called *Johnson*, an eminent painter of portraits, was born at Amsterdam, though, in the Chronological Tables, and in Sandrart, it is asserted that he was born in London; but he resided for several years in England, where he was engaged in the service of King James I. and painted several excellent portraits of that monarch, as also of his children, and of the principal nobility of his court. He had not the freedom of hand, nor the grace, of Vandyck; but in other respects he was accounted his equal, and in the finishing of his pictures superior. His paintings are easily distinguished by their smooth, clear, and delicate tints, and by that character of truth and nature with which they are strongly marked. He generally painted on boards; and his draperies are for the most part black, probably because the opposition of that tint made his flesh colours appear more beautifully bright, especially in his female figures. He frequently painted in a small size in oil, and often copied his own works in that manner. His fame began to be somewhat obscured on the arrival of Vandyck in England; and the civil war breaking out some time afterwards, induced him to return to his own country, where his paintings were held in the highest esteem. He died in 1685.

Janssens, *Abraham*, an historical painter, was born at Antwerp in 1569. He was contemporary with Rubens, and also his competitor, and in many of the finest parts of the art was accounted not inferior to that celebrated master. It is reported, that having wasted his substance by a life of dissipation and pleasure, and falling in consequence into necessitous circumstances, which, however, he imputed to ill fortune rather than to his own neglect of his business, he grew envious of the grandeur in which Rubens appeared, and, impatient of his merit and success, challenged him to paint a picture with him for fame alone. But Rubens rejected the proposal, answering with modesty, that he freely submitted to him, and the world would certainly do justice to them both. Sandrart, who had seen several of his works, assures us, that he not only gave a fine roundness and relief to his figures, but also such a warmth and clearness to the carnations, that they had all the appearance of real flesh; and his colouring was as durable as it was beautiful, retaining its original lustre for a number of years. His capital performance is said to have been the resurrection of Lazarus, which was in the cabinet of the elector-palatine, and an object of admiration to all who beheld it.

Janssens, *Victor Honorius*, an historical painter, was born at Brussels in 1664. He was a disciple of Volders, under whose direction he continued for seven years, during which time he gave many proofs of a superior genius. He afterwards went to Rome, where he studied particularly the works of Raffaelle. He designed after the antiques, and sketched the beautiful scenes around that city. In a short time his paintings rose in esteem, and the principal nobility of Rome were desirous to employ him. He associated for several years with Tempesta, the celebrated landscape painter, and painted the figures in the works of that great master as long as they resided together. Janssens composed historical subjects, both in a small and a large size; but he found the demand for his small pictures so considerable, that he was induced to paint most frequently in that size. He continued at Rome during eleven years, which barely sufficed for his finishing those pictures which he was engaged to paint; nor would he have even then been at liberty, had he not limited himself to a number, and determined not to undertake more. On his return to Brussels, his performances were as much admired there as they had before been in Italy; but having married, and become the father of eleven children, he was compelled to change his manner of painting in small, and to undertake only those of the large kind, as being more lucrative, more expeditious, and also more agreeable to his genius and inclination. He adorned with his compositions most of the churches and palaces of his own country.

JANUARIUS, St, the patron saint of Naples, where his head is occasionally carried in procession, in order to stay the eruption of Vesuvius. The liquefaction of his blood is a famous miracle, or rather juggle, at Naples. The saint suffered martyrdom about the end of the third century. When he was beheaded, a pious lady of Naples caught about an ounce of his blood, which has ever since been carefully preserved in a bottle, without having lost a single grain of its weight. This of itself, were it equally demonstrable, might be considered as a greater miracle than the circumstance on which the Neapolitans lay the whole stress, namely, that the blood, which has congealed, and acquired a solid form by age, is no sooner brought near the head of the saint, than, as a mark of veneration, it immediately liquefies.

JANUARY, the name of the first month of the year, according to the computation now used in the West. The word is derived from the Latin *Januarius*, a name given to it by the Romans from Janus, one of their divinities, to whom they attributed two faces, because on the one side the first day of January looked towards the new year, Janus || Japan.

and on the other towards the old one. The word *Januarius* may also be derived from *janua*, a gate; because this month being the first, is, as it were, the gate of the year. January and February were introduced into the year by Numa Pompilius, the year of Romulus having commenced in the month of March. The kalends of this month were under the protection of Juno, and in a peculiar manner consecrated to Janus by an offering of a cake made of new meal and new salt, with new frankincense and new wine. On the first day of January a beginning was made of every intended work; the consuls elect took possession of their office, and, with the flamens, offered sacrifices and prayers for the prosperity of the empire. On this day all animosities were suspended, and friends gave and received new year's gifts, called *Strenæ*.

JANUS, in the heathen worship, the first king of Italy, who, it is said, received Saturn into his dominions, after he was driven from Arcadia by Jupiter. He tempered the manners of his subjects, and taught them civility; and from him they learned to improve the vine, to sow corn, and to make bread. After his death he was adored as a god. This deity was thought to preside over new undertakings. Hence, in all sacrifices, the first libations of wine and wheat were offered to Janus; all prayers were prefaced with a short address to him; and the first month of the year was dedicated to and named from him. Janus was represented with two faces, either to denote his prudence, or that he views at once the past and approaching years. He had a sceptre in his right hand, and a key in his left, to signify his extensive authority, and his invention of locks. Though this is properly a Roman deity, the Abbé la Pluche represents it as derived from the Egyptians, who made known the rising of the dog-star, which opened their solar year, with an image having a key in its hand, and two faces, the one old and the other young, to typify the old and new year.

Temple of Janus || Japan.

Temple of Janus, in ancient history, a square building at Rome, erected by Romulus, and so large as to contain a statue of Janus five feet high, with brazen gates on each side, which were always kept open in time of war, and shut in time of peace. But the Romans were so much engaged in war, that this temple was shut only twice from the foundation of Rome till the reign of Augustus, and six times afterwards.

JAPAN.

The extensive and powerful empire of Japan consists of several large islands on the eastern coast of Asia, which extend in a direction north-east and east-north-east, from the 30th to the 41st degrees of north latitude, and from the 129th to the 143d of east longitude. The largest of these islands is called Niphon, which name is also sometimes applied to the whole empire. It is about 700 miles in length, though not more than eighty in breadth, and runs lengthwise from east to west in a winding form. It is separated by a narrow channel full of rocks and islands, several of them uninhabited, from Sikokf, next to it in size, and which is ninety miles long and fifty broad. The third island, Kiusiu, of a square figure, and divided into four provinces, lies between the other two, and is 200 miles long by 140 broad. These islands are surrounded with numerous others, generally small, rocky, and barren; some of them, however, large, rich, and fruitful, and governed by petty princes. There are several other islands which are subject to the authority of Japan, though they form no integral part of the empire. Among these is the large island of Jesso, which has been colonized by the Japanese, and is the most northerly island they have beyond their own empire. The coasts are rocky and mountainous, and they are washed by a tempestuous sea, which, by reason of its shallowness, admits none but small vessels, and even these not without imminent danger, the depth of most of its gulfs and harbours being not yet known, and others that have been sounded being too shallow for ships of any bulk. Several dangerous whirlpools also occur amongst the rocks and shallows, by which vessels are frequently drawn in and dashed to pieces. It is remarked by Kæmpfer, in his ample and accurate account of Japan, that nature seems purposely to have designed these islands to be a sort of little world, separate and independent of the rest, by making them difficult of access, and by endowing them plentifully with all that is necessary both for luxury and comfort, and thus enabling them to subsist without any commerce with other nations. The Japanese policy, of rigidly forbidding all intercourse with strangers, which, in other circumstances, might have been difficult, if not impracticable, has been greatly facilitated by these natural advantages of the country.

The country, climate, and produce.

These islands are in general rugged and irregular in their surface, intersected by ranges of lofty mountains, which are frequently steep and broken into precipices. Some of the mountains rise to a great elevation, as the mountain of Fusi, in the southern part of Niphon, which is considered to be the most elevated, and is covered with perpetual snow. In the northern part of the same island are also extensive and lofty mountains. The narrow valleys between these mountains are generally fertile and well cultivated; but the greater part of the country is rocky and barren, and it is only by the indefatigable care and industry of the natives that it has been rendered productive, and that it yields an abundant supply of food. The great staple of agriculture is rice, of which there are several varieties: the best sort is perfectly white like snow, very nutritive, and when boiled is used at meals instead of bread. A certain sort of bean, of which they make a mealy pap, and use in the dressing of victuals as butter is used in Europe, is held in much esteem. Barley, which they call great corn, is cultivated, though not in great quantities: they use it in the feeding of cattle and horses, whilst others dress their victuals with the flour, or make cakes of it. One sort of barley, which grows in Japan with purple-coloured ears, gives a very pleasing aspect to the fields. Wheat, which is called small corn, is extremely cheap, and is baked into a particular sort of cakes, though it is but little used. Peas, beans, and Indian corn, are cultivated; and almost all the varieties of nutritious grains and pulse. Turnips grow plentifully in the country, and to a large size. Horse-radish, carrots, gourds, melons, cucumbers, parsnips, fennel, and some sorts of lettuce, grow wild; and parsley and other vegetables, which are cultivated by the Dutch, thrive well. There are numerous other plants, which grow in the fields, the woods, and forests, and in marshy grounds, of which the leaves, roots, or the flowers and fruits, afford sustenance for the common people, and even luxuries for the great.

The Japanese excel in agriculture. Being cut off from all intercourse with other nations, they rely on their own resources; and this, with the extreme populousness of the country, gives a stimulus to cultivation, as well as to every other branch of industry. Not only are the fields and flat country laid out in the cultivation of rice, being seldom converted into pasture, but likewise the hills and mountains afford corn, rice, peas, pulse, and numerous other edible plants. Every inch of ground is improved to the utmost; and it is mentioned by Kæmpfer, that he beheld, in his journeys to and from court, hills and mountains, many of them inaccessible to cattle, which would lie wholly neglected in other countries, cultivated to their tops. The law on this subject is strict and severe, enforcing on all the cultivation of the ground as a sacred duty, and punishing the neglect of it by the forfeiture of the land. The flat grounds are ploughed with oxen, the steep and high ones by men; and, where they have the command of water, the rice-grounds are intersected by canals. The rent of the landlord is reckoned at six tenths of the gross produce; and, with the view of accurately estimating the amount, surveyors are appointed, who, before the harvest, compute the probable returns with surprising accuracy, with a view to a just division of the produce.

From the laborious culture to which they are subjected, the Japanese islands abound in a great variety of useful and beautiful trees and plants. Amongst the most curious and finest trees is the varnish tree. It affords a milky juice, with which the inhabitants varnish, or, as we call it, japan, all their dishes and plates of wood, from the emperor to the meanest peasant; for, even at court, services of lackered ware are preferred to those of gold and silver. The mulberry tree grows in most parts of Japan, especially in the northern provinces, where many cities and villages depend almost wholly on the silk manufactures, though the silk which they weave is not the finest, nor equal to the Chinese silk. The tea shrub is one of the most useful plants growing in Japan; it is planted round the borders of rice and corn fields, and in barren places unfit for the culture of other things. All ranks drink of an infusion from this shrub; and it is the custom of the country to present it when friends come to visit, both when they come and when they depart. The common people use the coarser leaves, the young and tender leaves being used by the higher classes. The laurel tree is common in Japan. That which bears red berries resembles the cinnamon tree in shape, and in the figure and substance of its leaves; but the bark wants the peculiar sweetness of the true cinnamon tree, an imperfection which Kæmpfer ascribes to the quality of the soil. The camphor tree is found in Japan; and the *sansio*, the leaves of which are eaten on account of their pleasant aromatic taste. Firs and cypress trees are common in the woods. They are planted in barren and sandy places which will produce nothing else, or along the roads, which makes travelling very pleasant. The wood is used in the construction of houses, ships, and household articles, and the branches for fuel. There are other hard woods, such as the oak, which is different from the European oak, and of which there are two varieties; and the iron tree, of which houses are generally built; and others that have a fine grain, and are used for cabinets, chests of drawers, &c. The baraban is common, and is of great use here, as also in India. Fruits in great variety and abundance are found in Japan; figs of different sorts, oranges, lemons, citrons, grapes, chestnuts, walnuts, nuts of different kinds, peaches, apricots, plums, brambleberries, strawberries, raspberries, &c. Cherry trees, apricot trees, and plum trees, are valued for the sake of their flowers, which, under proper culture, become large and luxuriant, and when they are in full blossom form a fine ornament around their temples, in their gardens, and in their walks, the trees being thickly covered with flowers, as with snow.

Japan is distinguished above all other countries for the great variety of beautiful plants and flowers which adorn its fields, hills, woods, and forests, and which, when they are transplanted into gardens, and improved by assiduity and culture, attain to a surprising degree of perfection. They mostly resemble either the rose or the lily. There is a large shrub, called tsubacki, which grows in woods and hedges, of which there are many beautiful varieties, and for which there are about 900 names in the Japanese language. Of the shrub called satsuki, with lily flowers, which is to be met with in the gardens, there are a hundred varieties. Sakanandsio, another shrub with lily flowers, of which there are only three varieties, is much larger than the former. There are numberless other flowers, some forming the chief ornament of houses and gardens, others of desert and uncultivated places. But of all these flowers, it is observed by Kæmpfer,[1] that as they exceed those in other countries in the show and exquisite beauty of their colours, they are greatly inferior to them in scent and fragrance. The same is also true of the fruits in Japan, which are far from equalling the pleasant aromatic taste of those which grow in China and other eastern countries.

The country is plentifully supplied with fresh water from the many fountains, lakes, and rivers which are scattered throughout the empire. There is no space in the country for the formation of great or navigable streams; but some of the rivers are so large and rapid, from the mountainous and rocky channels through which they make their way, and from the profuse showers of rain which frequently fall in the upper regions, that they are not to be passed without danger, arising from the impetuosity of their currents.

The climate of Japan, though it is upon the whole salubrious, is subject to frequent changes. The country lies without the range of the monsoons and the periodical rains; and accordingly it rains frequently throughout the whole year, but with the greatest profusion in the months of June and July, which are for this reason called the water-months. During the winter the ground is covered with snow, and there are often sharp frosts, whilst in the summer it is intolerably hot. At Nagasaki the thermometer ranges from 98° to 35°. Thunder and lightning are very frequent. Earthquakes are common, and happen so frequently that the inhabitants are familiarized to those dreadful phenomena when they are not uncommonly violent. Sometimes, however, the earth is shaken with so violent a commotion, which lasts so long, that whole cities are thereby destroyed, and many thousands of the inhabitants buried in the ruins. A great earthquake happened in the year 1586, when the earth yawned, and swallowed up one half of Nagafama, a small town containing 1000 houses; and the sea, violently breaking over its usual boundary, overflowed the rich and populous town called also Nagafama, and drowned all the inhabitants, besides destroying other smaller towns. Another occurred in 1703, by which, and by a great fire which happened at the same time, the whole city of Jedo was destroyed and laid in ashes, and about 200,000 inhabitants perished in the ruins. Some parts of these islands are entirely free from these concussions. Volcanoes are found in different parts of Japan, indicating the presence of those combustible materials which are imprisoned in the bowels of the earth, and which, suddenly bursting forth, and forcing an outlet, occasion earthquakes. Not far from Firando, where the Dutch had their factories before they removed to Nagasaki, lies a small rocky island, which has been burning and trembling for many centuries. Many mountains emit a perpetual flame. From the famous mountain of Fusi, which, Kæmpfer observes, is only surpassed in height by the Peak of Teneriffe, but "in shade and beauty hath not its equal," and which is covered with everlasting snow, a

[1] Vol. i. chap. ix. p. 119.

Japan. black stench and smoke is observed to issue, the remains of its half-extinguished volcano, which formerly burned with a brighter flame. In many places the soil is burning hot, and is besides so loose and spongy, that it makes a cracking and hollow noise under the foot. Hot and sulphureous springs abound in the vicinity of these burning mountains, and are prescribed as specifics in many complaints.

Minerals. Japan abounds in mineral wealth; in all the metals, besides various useful minerals. Gold is found in several provinces of the empire, and is smelted from its own ore. It is gathered from the sands of several of the rivers, and is also found combined with copper. The richest mine, which also yields the finest gold, is situated in one of the northern provinces in the great island of Niphon; and here also is a very rich gold sand, which the prince of the district causes to be washed for his own benefit. Next to these the gold mines of Surunga are esteemed the richest; and here gold is found in all the copper that is dug up. There are other mines, affording ore which is productive, and would repay the labour of working; but some of them are filled with water, and the uninstructed natives know of no process for drawing it off. Silver is found in different parts, particularly at Kattami, in one of the northern provinces; but it is not so abundant as gold. The metal which is most important to the trade of Japan, and is also most abundant, is copper. There are very rich copper mines in different provinces of the empire; in Surunga, Atsingo, and Kijnokuni. The copper found in the mines of the latter place is the finest, most malleable, and fittest for work, of any in the world; and in some cases, as already mentioned, it contains a considerable quantity of gold, in the refining of which the Japanese have greatly improved. All the copper is brought to Saccai, one of the five imperial towns, where it is refined and cast into small cylinders. These are packed up in square boxes, and sold at a high price to the Dutch, copper being one of the staple articles of export from Japan. There is besides a coarser sort of copper, which can be bought at a lower price than the other, being much inferior in quality and appearance. Brass is very scarce in Japan, and brings a much higher price than copper. A small quantity of tin is found, but so exceedingly white and fine that it is almost equal to silver. This metal, however, is little used in the country. Iron is found in very large quantities on the confines of three provinces. It is refined on the spot, and is cast into cylinders two spans in length. It is fully as dear as copper; and household articles, hooks, and cramp-irons in buildings or in ships, which in other countries are made of iron, are in Japan made of copper or brass. In dressing their victuals they use a particular sort of kettles or pans, made of a composition of iron. The art of making this composition has been lost, so that the old articles of this sort bring a high price.

Of mineral substances, sulphur is found in great abundance. It is dug up in a neighbouring island, which, from the great plenty it affords of this substance, is called Sulphur Island. This island was formerly considered as inaccessible, by reason of the thick smoke which was observed continually to arise from it. But this fear having been overcome, its produce now yields a revenue to the prince of Satzuma, of about twenty chests of silver per annum. Coal abounds in the northern and several other provinces. Salt is made of sea-water; and it does not appear that they have any mineral salt. Agates of several sorts, some of them extremely fine, of a bluish colour not unlike sapphires, as also cornelians and jaspers, are brought from the northern extremities of the great province of Osju, opposite to the country of Jedo. Naphtha is found in one of the rivers, and is taken up where the water has little or no run, by the natives, who burn it in lamps instead of oil. Some ambergris is obtained upon the coasts of Satzuma, and of the Riuku islands. It is found chiefly in the intestines of a whale which is caught frequently on the Japanese coasts, or floating on the surface of the sea, being torn up from the bottom by the violence of the waves. Pearls are found throughout almost the whole circuit of the island, in oysters and several other kinds of shell-fish; and every one is at liberty to fish for them. The largest and finest pearls are found in a small sort of oyster, called akoja, which is not unlike the Persian pearl shell, about a hand broad, exceedingly thin and brittle, and shining on the outside, but within of a whitish colour, and glittering like mother-of-pearl. All sorts of submarine plants, shrubs, corals, stones, mushrooms, sea-fans, corallines, fuci, algæ, and the like, as also shells of all kinds, are found plentifully in the Japanese seas, and nowise inferior in beauty to those found about Amboyna and the Spice Islands. These are, however, very little valued by the inhabitants.

Animals. Japan does not abound in animals, either wild or tame. This may be accounted for from the extent of cultivation, which leaves little room, and no great cover, for the wild animals; and the tame animals, not being used as food by the inhabitants, are not multiplied beyond the necessary uses for which they are designed. The horse serves for purposes of state, for riding, for carriage, and for ploughing. The breed is small; but some of them are not inferior in shape, swiftness, and dexterity to the Persian breed. A certain breed of little horses is very much esteemed. Oxen and cows are only used in ploughing and carriage. The people care nothing for milk or butter, which are not used as articles of food. They make use of a sort of large buffaloes, of an extraordinary size, with hunches on their backs like camels, for carriage and transport of goods. Of asses, mules, camels, and elephants, they know nothing. Sheep and goats were formerly kept at Firando by the Dutch and Portuguese, and might be bred in the country to great advantage if the natives were permitted to eat their flesh, or knew how to manage or manufacture their wool. They have few swine, and these few are brought from China, and bred for the use of the Chinese, who make an annual resort to these islands, and amongst whom they are in great demand. It is mentioned by Kæmpfer, that whilst he was in Japan, dogs had multiplied in an extraordinary degree, owing to the partiality of the reigning emperor for that animal, in consequence of his being born in the sign of the dog. Greyhounds and spaniels are not known. The wild animals are deer, bears, wild boars, hares, foxes (which the natives hold in abhorrence, supposing them to be animated by demons), monkeys, wild dogs, a small animal called itutz, of a reddish colour, another called tin, both living in houses, and lodging themselves under the roofs, and so tame that they may be ranked amongst the domestic animals. The whole country swarms with rats and mice; the former animal is frequently tamed, and taught to perform several tricks for the amusement of the inhabitants.

All the varieties of the feathered race are met with in these islands. The falcon species are found in great numbers in the northern provinces, and are kept more for state than sport. Ravens, cranes, herons, wild geese, ducks, pheasants, wood-cocks, wild pigeons, storks, snipes, sparrows, swallows, larks, nightingales, &c. are common. The crane is protected by the particular order of the emperor, and can only be shot by his express commands, and for his own especial use. There is a singular species of duck, which is distinguished by the most surprising beauty of plumage. The pheasants are also of uncommon beauty. Neither the common European crow nor the parrot is to be met with in Japan. Snakes are seen, some of them of an enormous size; and insects are numerous and troublesome, especially the white ant, which is known for its de-

Japan. structive qualities; also scorpions and other noxious reptiles.

The Japanese have invented, or borrowed from their neighbours the Chinese, a great many fictitious animals, which are either allegorical or connected with their mythology. The kirin is a winged quadruped of incredible swiftness, with two horns standing before the breast; its good nature and holiness are such that it takes care, even in walking, not to trample on any the least plant, nor to injure the most inconsiderable worm or insect. Besides this animal there are other chimerical creatures of the quadruped kind, to which the Japanese ascribe various imaginary qualities. Of these the dragon is the most remarkable, and the chronicles and histories of their gods and heroes abound in fabulous stories of this animal, which is also employed in the armorial bearings of the emperor. Foo is a beautiful large bird of paradise, somewhat resembling the phœnix of the ancients. It dwells in the higher regions of the air, and never descends, as the Japanese believe, to honour the earth with its blessed presence, except at the birth of an emperor, or at that of some such distinguished personage.

Government, laws, and institutions.

All our knowledge of the Japanese government and laws is derived from Kæmpfer and Thunberg, who accompanied the Dutch in their annual commercial visit to these islands, the one in the year 1690, and the other in 1775. The account of Kæmpfer is exceedingly full and accurate, and its accuracy is attested by Dr Ainslie, one of the British commissioners, who, in 1810, when the island of Java was in possession of the British, had been sent by Sir S. Raffles to accompany the Dutch ships on their annual visit to Japan. They were, however, strangers, ignorant of the language, and hence were but imperfectly qualified to describe with accuracy the political institutions of this state. Throughout all Asia pure despotism is the prevailing form of government, and to this Japan forms no exception; but, according to the accounts of Kæmpfer and Thunberg, it is subjected to the double rule of a spiritual and a political sovereign, the respective limits of whose jurisdiction and duties do not appear to be very distinctly marked. Kubo is the name of the secular, and Dairi of the ecclesiastical emperor. To the latter are paid almost divine honours; but the real power of the state appears to be vested in his political competitor. The power of the sovereign is supreme; it is restrained by no positive law, though, as in all despotic countries, it may be tacitly modified by custom and immemorial usage. The emperor, according to Kæmpfer, inherits, along with the crown, an absolute and unlimited power over all his subjects, from the meanest peasant to princes of the highest rank. As in all the eastern countries, where the art of government is in its infancy, the country is divided into large tracts of land, which are again subdivided into sixty-eight considerable provinces, and these again into 604 smaller districts or counties. The provinces are ruled by governors or princes appointed by the emperor. These governors are amenable, for the exercise of their delegated authority, to the supreme head of the empire, who may dismiss or banish them, and even inflict on them capital punishment. They are entitled to the revenues of their provinces, with which they maintain their rank and state, besides a military force for the maintenance of order, and out of which they also keep the roads in repair, and carry on all other necessary improvements. They are also bound to repair once in the year to the court, with all due splendour, and a great retinue, and to bring with them considerable presents, and, according to the jealous maxims of despotic countries, to leave their families constantly at the court as hostages for their allegiance. The residence of these princes is mostly in the large and maritime towns, or those situated on rivers; which are surrounded by walls and ditches, the prince's castle standing most frequently at the extremity of the town, defended by strong gates and high towers.

The ecclesiastical was at first the only ruler that governed the kingdom. But his generals, to whom he was obliged to confide the command of his armies, gradually usurped the real power, leaving to the high priest only the empty splendour of the throne. Syn Mu, the founder of the monarchy, flourished 660 years before the Christian era. He improved both the government and the laws of the country. The emperors of his race were usually denominated Dairi; and a hundred and nineteen Dairis have ascended the throne in succession from that period down to the year 1775, when Thunberg resided in Japan. For more than 250 years the authority of the Dairi, the old and lawful potentate of the country, has been confined chiefly to ecclesiastical matters, though he is still held in the same veneration as ever. His person is considered as too sacred to be exposed to the air and the rays of the sun, and still less to the view of any human creature, and he is consequently confined within doors; and when he goes out of his palace, he is generally carried on men's shoulders, that he may not come in contact with the earth. His person is accounted so sacred, that his hair, nails, and beard, are never suffered to be cleansed or cut by daylight, an opportunity being taken to perform these operations when he is asleep. He never eats twice from the same plate, nor uses any vessel a second time. They are invariably broken to pieces, lest they should fall into unhallowed hands. The right of bestowing titles of honour is to this day vested in the person of the ecclesiastical emperor, and is a source of revenue. Even Kubo, the name of the political emperor, is honoured by the titles which he receives from this sovereign pontiff of Japan. Those who have spiritual titles are distinguished, both at court and in the churches, by a particular dress, conformable to their rank and dignity. So august and holy is Dairi considered, that Kubo, though possessing the real power, is bound, either in person or by his ambassador, to pay him an annual visit, and to bring presents in acknowledgment of his title to rule in the state. At the court of Dairi literature is cultivated. It is the only university in the country where students are maintained and instructed. Poetry, history, and mathematics are here cultivated; and music is a favourite study, especially with the fair sex. Here it is that all almanacs are compiled. The secular emperor derives his revenues from a tax on the produce of the land. These have been estimated, though on no very certain data, to amount to a sum equal to L.28,000,000. But this is probably a gross exaggeration. The military force is estimated at about 100,000 foot and 20,000 horse, whilst the different governors of provinces maintain each a large force within his respective territory. There seems little occasion for so large an establishment of troops, as Japan, being separated from all other countries by a stormy sea, is in no danger of attack from ambitious neighbours. The descendants of Genghis Khan, who conquered China, also invaded Japan with a great army; but they were completely repulsed by the valour of the inhabitants. Since this period the Japanese have been engaged in war with the Coreans, but with little effect. The domestic peace of the country has, however, been occasionally interrupted by the rebellion of the provincial governors, or by a disputed succession.

Laws and police.

The laws, as among all the half-civilized states of Asia, are implacable and severe. Death is the appointed punishment for almost every crime, sometimes by decapitation in prison, and, for higher offences, by impaling on the cross. Fines they consider as unequal and unjust, because they are less severe on the rich than on the poor; and from this absurd notion they confound in one common punishment all the different shades of crime. Where a

Japan. murder is committed in a town or in the open street, not only the criminal, but his relations and dependents, and even neighbours or spectators, according as they have been more or less cognisant of the crime, or have not interfered to prevent it, are rendered amenable to justice. The master of a house is in like manner held responsible for his domestics, and parents for their children; and this cruel and bloody spirit pervades the whole system of their criminal justice. If one man draws his sword on another, it is a capital offence; and smuggling of all kinds is invariably punished with death, buyers and sellers being involved in the same penalty. Some offences are punished by perpetual banishment and confiscation of goods. Every criminal has a fair trial before the proper tribunal, and by a careful examination of witnesses. The prisons are gloomy and horrid abodes; they contain an apartment for trial by torture, another for private executions, a kitchen, a dining-room, and a bath. The towns are subjected to a very strict police, in which the same rigour prevails as in the administration of justice; and the consequence is, that, through the influence of terror, the most exact order prevails, each petty delinquent still incurring the penalty of death. Four officers are appointed in every town, of which number one presides every year. A commissioner is besides appointed for every street, who keeps an account of deaths, births, and marriages, and makes his report to the head officer. He has the power of casting offenders into prison, and of even putting them in irons; and he employs spies, who bring them accurate intelligence of all that takes place.

Religion. There are two leading religious sects in Japan, namely, the Sintos and the Budsdos; though there are numerous other sectaries who hold the most opposite tenets, and yet live together in the greatest harmony. The religion of the Sintos is the more ancient of the two, and seems to be a system of polytheism, which, along with one Supreme Being, acknowledges a crowd of inferior deities, and often of deified heroes, who are supposed to exercise dominion over the earth, the water, the air, and over particular districts, and to have the power of making men either happy or miserable. They believe in a state of future rewards and punishments. The souls of the virtuous, according to their creed, dwell immediately under heaven; whilst those of the wicked are doomed to wander on the earth for a certain period, in expiation of their sins. The chief points of the Sinto religion are inward purity of heart, abstinence from whatever makes a man impure, and a diligent observance of solemn holidays, and of pilgrimages to holy places at certain seasons of the year. They abstain from animal food, and from the uncleanness of a dead body, and are loath to shed blood. Their system of divinity, according to Kæmpfer, is such a tissue of monstrous and absurd fables, that their priests are ashamed of it, even in the presence of their own adherents. Their notions of the creation of the world resemble the wild extravagances of the Hindus. Kæmpfer heard a sermon by one of their priests, which he describes as a confused composition of ridiculous stories and fables about their gods and spirits. The devils, they imagine, reside in the bodies of foxes; and this animal is accordingly held in general abhorrence by them. They have churches, in which they attend for worship on stated holidays. In these temples they have no visible idols, nor any image to represent the Supreme Being. But in the centre is generally placed a large polished mirror of cast metal, the purpose of which is to impress on those who worship, that as the mirror reflects a faithful image of their person, so the secret faults and impurities of the heart lie open to the all-searching eyes of the immortal gods. They never approach those temples unless they are perfectly clean; and accordingly they wash themselves with water, and, putting on their best apparel, they bow respectfully to the ground, preferring their prayers, and presenting their offerings. Kubo, the emperor, belongs to this sect, and is bound to pay a visit every year, either in person or by his ambassador, to one of their temples, and to make presents of great value, which is accounted the essence of piety by the priests of Japan, as by all other priests in every age and country. The doctrine of Budsdo, identical with Buddha, whose votaries are spread over the East, was brought from Continental India into China, and thence introduced into Corea and Japan, and, being mixed with the existing doctrines and practices of Sinto, gave rise to the most monstrous superstitions. The Japanese follow Buddha's doctrine of the immortality of the souls of men and of beasts, of a future state of rewards and punishments, and of the transmigration of the souls of men into animals. The churches of all the different sects are adorned with alleys of cypress trees, and handsome gates; and most of them have a separate chamber for their idol, where he is exhibited sitting on an altar surrounded with incense, flowers, and other decorations. The churches are open every day, but there are festival days throughout the empire, which are more especially appropriated to religious worship by both Sintos and Budsdos. These are the first and last days of every month, the new moon, and the first day of the year, which last is spent in eating and drinking, visiting the temples, and making merry. There is, besides these priests, a holy order of men called Jammabos, or Monks of the Mountain, devoted to religious exercises and holy contemplation; and an order of blind monks, who are dispersed all over the empire. Religious vows are frequently made by devotees; and in this, as in many other points, the Japanese superstition resembles that of Hindustan and other eastern countries. It is related of one of these persons by Thunberg, that having made a vow never to make use of shoes, he actually accompanied the Dutch embassy to the imperial court, walking on his bare feet, though it was the depth of winter. Kæmpfer also mentions, that sometimes persons are met with in the streets running about quite naked, according to vows which they have made to visit in that state certain temples, provided they obtain by the mercy of the gods deliverance from some fatal distemper they themselves or their relatives have been subject to, or from other great misfortunes with which they are threatened. Multitudes of religious beggars, with their heads shaved, also crowd the streets; and to this tribe belong a singular religious order of young girls, who, if they be handsome and agreeable, easily obtain the privilege of begging in the habit of nuns. They watch particularly people of fashion, and accost them by singing a rural song; and if they prove liberal, they will accompany them for hours. Their voice, gestures, and apparent behaviour, are neither too bold nor daring; but free, comely, and seemingly modest. Kæmpfer, however, intimates his idea of their true character, under whatever specious appearances it may be disguised. Nunneries have been established in the country upwards of a thousand years. Besides these idolatrous devotees, there is a sect of philosophers, who deride the popular worship, and merely inculcate the duty of leading a holy and virtuous life, and the belief of one great first cause, the divine author of all things.

The Dairi is the spiritual head of the Sinto religion; and since the retrenchment of his power the secular emperor has granted for the maintenance of his state and dignity the whole revenue arising from the city of Miaco and the adjacent districts. He has likewise an allowance from the imperial treasury, besides immense sums which he derives from his privilege of conferring titles of honour. But these allowances are not nearly so great as when the Dairi possessed the secular as well as the eccle-

Japan.

siastical power, and they fall short of the necessary expenses of his court. Hence many of his retainers are compelled to work at menial employments to procure a livelihood; and Kæmpfer describes his court as being only remarkable for its splendid poverty.

Revenues.

The public revenue is derived, as far as we can gather from the necessarily imperfect accounts of those who have visited Japan, from a land-tax, and a tax on houses. The land is rated according to its produce, consisting for the most part of rice. The arable land is divided into three classes, according to its fertility; and the public tax amounts to more than one half, or even to two thirds of the produce. The land belongs to the crown, whose rights or claims none dare dispute; and unless the farmer cultivate it with care and attention, it is taken from him. In the towns each proprietor of a house is assessed in proportion to the breadth of his house towards the street, besides presents which are exacted from him by the civil officers, and taxes for the support of the temples and idols. The land-tax is collected by the receiver-general.

National character and manners.

The national character of the Japanese, as described by Kæmpfer, Thunberg, and others, has been corroborated by Dr Ainslie, who, by order of Sir Stamford Raffles, accompanied the Dutch in their annual visit to these islands in 1812. He describes them as a nervous, vigorous people, assimilated by their bodily and mental powers much nearer to Europeans than to Asiatics. The traits of a vigorous intellect are displayed in the greater progress they have made in the sciences and in the arts, which are carried to a much higher degree of perfection among them than among the Chinese, with whom they are frequently confounded, but to whom they consider it as a great disgrace to be compared; and the only occasion in which Dr Ainslie saw a Japanese surprised into a passion, and, relinquishing his habitual politeness, lay his hand on his sword, was on an unguarded comparison being made between the two nations. Thunberg represents the Japanese as frugal, ingenious, sober, just, and friendly; yet distrustful, superstitious, proud, and implacable in their resentments; never forgiving an injury, but carefully concealing their hatred, and patiently waiting the favourable moment for striking their victim to the heart. This deep-rooted malignity is a common feature in the character of all barbarous nations; and hence the feuds that we hear of among them are handed down from generation to generation. This spirit of revenge arises from pride, and that lofty sense of honour by which the Japanese are distinguished. Thunberg, in depicting the character of this singular people, appears to ascribe to them qualities which are scarcely consistent with their state of improvement. He speaks of a love of liberty, not that liberty, he adds, which degenerates into licentiousness, as being the passion of the Japanese, who nevertheless enjoy no freedom, but are subjected to cruel laws and to the caprice of a tyrant, at whose mercy they hold both their lives and properties. The love of freedom can scarcely exist in a community so degraded; it can only flourish amongst a refined people, guarded by equal laws against the violence of power. Ceremonious manners, another feature of a comparatively rude and ignorant people, are much cultivated by the Japanese. In courtesy and submission to their superiors, few can be compared to them. Inferiors are accustomed to bow to the class above them, lowly and reverently; a consequence, probably, of severe laws, and of the habitual bondage in which the lower classes are held by their superiors. But the intercourse between equals in rank is also encumbered with a variety of troublesome ceremonies; a sure mark that true refinement has made little progress, seeing that, as mankind gradually improve, they insensibly relinquish these impediments to social intercourse, as inconvenient and absurd. The Japanese are extremely curious and inquisitive concerning the manners and habits of strangers; they are continually asking the Dutch for information, and wearying them with questions. It is related by Thunberg, that during the audience they had of the emperor, they were surveyed from head to foot by privy councillors and others, the higher officers of the state. Their hats, swords, clothes, buttons, lace, watches, and other articles of dress, were duly examined; and they were requested to write in the presence of the courtiers, that they might see the European characters and mode of writing. They are of friendly dispositions, of frugal and industrious habits, and honest in their dealings. Highway robberies are unknown, and thefts are seldom heard of, which perhaps may be partly ascribed to the severity and unrelenting vengeance of their laws. Dr Ainslie agrees with former writers in his representation of the Japanese as exhibiting an apparent coldness, like the stillness of the Spanish character, "eager of novelty, and warm in their attachments, open to strangers, and, bating the restrictions of their political institutions, a people who seemed inclined to throw themselves into the hands of any nation of superior intelligence. They have at the same time a great contempt and disregard of everything below their own standard of morals and habits, as instanced in the case of the Chinese." Nor, according to Dr Ainslie, is that uniformity observable amongst them which prevails amongst the Chinese, where the heavy hand of the government may be said to have broken down all individuality, and left one Chinese the counterpart of another. Unlike the Chinese, also, and unlike all other eastern nations, women are not immured at home; they go abroad like the ladies in Europe, and mix freely in society. Whilst Dr Ainslie resided at Nagasaki with the Dutch, frequent invitations and entertainments were given; and at one of these entertainments a Japanese lady from the court of Jedo is represented to have done the honours of the table with "an elegance and address that would have graced a Parisian."[1] In many important points they appear to have been misrepresented by the Dutch, for their own interested purposes. That their illiberality in religious matters, and their hatred and intolerance of Christianity, have been greatly exaggerated, is fully proved by the mission of Dr Ainslie. The story told of the annual ceremony of trampling on the crucifix as a test of their abhorrence of the Christian faith, was derided as a fable when it was mentioned to the priesthood. The Japanese were formerly adventurous navigators; they served as mercenaries throughout all Polynesia, and traded with all nations. They undertook voyages in their own vessels to Corea, China, Java, Formosa, and other places. They have since adopted an entirely different policy, and have rigidly forbidden all intercourse with other nations; and being in this manner confined within the limits of their own territory, their voyages are all along the coast, in trading vessels of different sizes, and in fishing smacks. The art of navigation has accordingly declined; and though they are provided with a mariner's compass, they seldom venture to lose sight of land. The natives are prohibited, on pain of death, from leaving their country, or from encouraging the visits of foreigners. The reasons of state which have induced the government to act upon these illiberal maxims are not well understood. Certain it is that the people do not participate in this jealousy of foreigners; they would willingly trade with them, and on all occasions evince the most frank and so-

cial dispositions. There is every reason to believe that this aversion of the Japanese government to all intercourse with strangers has been aggravated by the interested misrepresentations of the Dutch, anxious to monopolize the lucrative trade of Japan, and to banish all competition, by instilling into the rulers of the country a jealousy and a dread of all other Europeans. The ill treatment experienced by the mission from Russia in 1814, under Count Kreusenstern, is ascribed to the exclusive influence of the Dutch factory, who continued to "rain upon them," says Dr Ainslie, "through the medium of an interested and avaricious factor, who dreaded competition, every possible ignominy which can be supposed to have flowed from the despotism of Japan." They were lodged in a warehouse, which was pointed out to Dr Ainslie, who observes, that as "the rats were let out, the count and his suite were let in, where they remained for six long months, with scarce room to turn, the mark of obloquy to the Japanese, and the laughing-stock to the European factory." So deep an impression did the degrading treatment of the Russian embassy, and their meanness in submitting to it, make on the Japanese, that the chief officer asked the English commissioner if he would condescend to play the part of the Russian count; and, answering his own question, said, "No, I trust not." The insolence of the semi-barbarous nations of the East, such as the Japanese and the Chinese, which naturally leads them to trample on their European visitors, is best opposed by a spirited conduct, which inspires respect. Mean submissions, far from conciliating, only provoke fresh aggressions; as has been often proved in the intercourse of the Europeans with both Japan and China.

The Japanese are a proud, a brave, and a warlike people. Their arms consist of bows and arrows, scimitars, and guns. Their bows are very large, and their arrows long; and in discharging them the troops always drop down on one knee. Guns are not their usual weapons; and Thunberg mentions, that during all the time he was in Japan he never saw one discharged. They have cannon, but these are only fired every seven years; and so inexpert are the gunners, that they provide themselves with a long pole, and stand with averted eyes when they are firing off the gun. The scimitar, which is constantly worn by every one but the peasants, is their trusty weapon; it is a yard in length, of an incomparably good temper, and far surpassing the Spanish blades, which are so much renowned in Europe. With this weapon a Japanese will cleave his adversary asunder at a blow. In sciences and the useful arts the Japanese are far behind the Europeans. They study astronomy, but are unable, without the aid of the Chinese and Dutch almanacs, to compute a perfect calendar. They have made little or no progress in natural philosophy and chemistry, and even the scanty knowledge which they have acquired is borrowed from Europe. They appear to have studied botany and zoology with more success; and they have extensive works on these sciences, in which all the indigenous plants and animals are described, and exhibited in well-coloured plates. They have studied surveying, and possess maps of their own country, and of its towns, which are sufficiently accurate in topography, but without the divisions of longitude or latitude. When Dr Ainslie was at Nagasaki, a large detachment of officers of rank had just arrived, with a numerous and splendid retinue, who had been four years engaged in making a practical survey of every part of the empire and its dependent isles. "The survey," says Dr Ainslie, "appeared to be conducted on a scientific plan, to be most minute and accurate in its execution, and to have for its object a regular geographical and statistical survey of the country."[1]

Nor are their literary acquirements inconsiderable. They study the history of their own country, and their annals are said to be more authentic than those of most other eastern nations. They have also translated several European works, and appear to be familiar with the account which Kæmpfer gives of Japan, as they observed to the English commissioner, Dr Ainslie, that he was the very apostle of their faith, from whose works they knew even their own country. They have a college for interpreters, who study foreign languages; and it is an extraordinary fact, that, notwithstanding the determination of the empire not to enter into foreign commerce, an edict of the emperor has been issued, enjoining on the college of interpreters the study of the English language; and it has accordingly been cultivated with success by the younger members of the college, who are extremely anxious in their inquiries after English books. Amongst other works in the English, they showed to Golownin, Benyowsky's Conspiracy and Escape from Kamtschatka; an Account of the Expedition of the Russians and English to Holland in 1799; and a Geographical Description of the Russian Empire. The art of printing has long been known amongst the Japanese. They have also some knowledge of engraving; but in the art of drawing they are greatly inferior to Europeans. Poetry is employed by them chiefly to perpetuate the memory of their gods and heroes; and though music is held in high estimation amongst them, they have neither brought their musical instruments to any degree of perfection, nor do they understand musical science or harmony.

Although the Japanese in general are grave in their demeanour and manners, yet they frequently indulge in sports, festivities, and theatrical amusements. They have stated religious festivals, sometimes in honour of a particular god, which they celebrate not merely with devotional exercises, such as sermons and prayers, but with games, processions, public dances, and dramatic representations. These last are of the lowest description, consisting of exhibitions calculated rather to terrify than to entertain the audience. Artificial contortions of the body, and uncouth and extravagant dresses, seem to make up the whole amusement on these occasions. The story is generally some heroic exploit, or some adventure of their idols and heroes, composed in verse, and accompanied with music; diversified with low juggling tricks, which appear to be well adapted to the capacity of the audience. There are no decorations or machinery, nor any thing in these exhibitions which can put them on a level with the theatrical amusements of Europe. Weddings and funerals are celebrated with great pomp and many ceremonies, though the ceremony by which the married pair are united is short and simple. The bridegroom and bride advance together to an altar erected for the purpose, each holding a torch; and whilst the priest recites a form of prayer, the bride lights her torch from a burning lamp, and holds it to the bridegroom, who lights his torch from hers; upon which the guests congratulate the new married couple. Their manners are far from being pure. Many of the women live for a time with Europeans and others, receiving the wages of prostitution; and afterwards, in the full knowledge of their character, they are well married. The Japanese either bury their dead in the earth, or burn the body to ashes. The latter method is not so common as formerly, but is still practised by persons of distinction.

Public schools are established, in which children are in-

[1] See *Life of Sir Stamford Raffles*, p. 184.

structed in reading and writing, and are educated without chastisement or blows.

In many arts and manufactures they have made great progress, and some they have brought to such perfection as even to surpass those of Europe. They excel in the manufacture of copper, iron, and steel, of which the temper of their swords affords the best proof; and their silk and cotton manufactures are greatly superior to those of the other eastern countries. Their lackering of wood, especially the ancient workmanship in this line, and which derives its name from their country, surpasses every attempt at imitation by any other nation. Their lackered ware consists of the finest sort of firs and cedars, whieh they cover with the very best varnish, prepared from the *rhus vernix*, a tree that grows abundantly in many parts of the country. This varnish, which oozes out from the tree on its being wounded, is of so transparent a nature that every vein of the wood may be distinctly seen through it. In general a dark ground is spread under it, which causes it to reflect like a looking-glass; or it is mixed with some darker substance, and sometimes with gold leaf ground very fine, and is embellished with gold and silver flowers, and figures laid on upon the varnish. All articles made of wood, drawers, chests, boxes, scimitars, fans, tea-cups, and soup-dishes, the posts of their doors and windows, and most articles of household furniture, are covered with this varnish. They are acquainted with the art of making glass, coloured as well as uncoloured; they also grind glass for telescopes, for which purpose they purchase mirror-glass of the Dutch. Paper of all sorts is manufactured abundantly in the country, both for writing and printing, as well as for tapestry; and all coarser qualities for the packing of goods. It is prepared from the bark of a species of mulberry tree, which, by an ingenious process, is reduced to the consistence of a fine pulp, from which the sheets of paper are obtained. Japanese porcelain or china ware is manufactured out of a whitish fat clay, which is found there in great plenty. This clay requires a great deal of kneading, washing, and cleaning, before it acquires that degree of transparency which is the perfection of china ware; and the manufacture is altogether so laborious and troublesome, as to have given rise to the saying, "that human bones are an ingredient of China ware."

The temperature of the Japanese islands is in general salubrious. The most common diseases are colic, occasioned by the immoderate use of rice beer, which occasions violent pains, and often leaves behind it swellings in different parts of the body, and is especially productive of the hydrocele; red and watery eyes, occasioned amongst the poorer classes by the smoke in their confined apartments; and indurated glands, which frequently turn to cancers, dysenteries, small pox, measles, rheumatism, gout, pleurisy, water in the head, and certain eruptions on the skin. The physicians have no great knowledge of medicine, and their remedies consist generally of decoctions, diuretic or sudorific. Some profess only medicine, others the cure of internal disorders; and others, again, practise surgery, though they have no knowledge of anatomy. There is a class of persons for puncturing with needles, or for burning with a powder made from the dried leaves of a particular tree called *moxa*, which, being laid on the body, is set on fire, and burns the skin, leaving a scar behind it. Those who perform the operation of puncturing with needles may be heard in the evening patrolling the streets, and making a tender of their services with great noise and vociferation. The burning with *moxa* and puncturing with needles are supposed to be efficacious both for the prevention and cure of diseases; and they are resorted to by all classes, by rich and poor, old and young, especially in cases of pleurisy, gout, rheumatism, and toothach.

The Japanese, in selecting their food, range over the whole of the animal and vegetable kingdoms, using not only what is wholesome and nutritive, but some articles also which are poisonous, though, by their mode of preparation, they contrive to render these not only harmless, but useful. Their meat is always cut into small pieces, thoroughly boiled and stewed, and mixed with agreeable sauces. They sit at meals on soft floor mats, with a small square table before each guest; and the meat is served up in the neatest vessels, either of porcelain or japanned wood, furnished with a lid. The servant who attends kneels down as he places the dishes on the table and takes them away after dinner. They drink the soup out of the cup in which it is served; and they eat the solid parts of the meat with two lackered pegs, which they hold so dexterously between the fingers of the right hand, that they can with the greatest nicety take up the smallest grain of rice, these pegs serving them as both fork and spoon. The company, before beginning to eat, salute each other with a low bow; and the ladies, says Thunberg, eat separately from the men, though this scarcely agrees with Dr Ainslie's account of the lady whom he commends for doing the honours of the table at an entertainment where he was present, with all the grace of a Parisian. Tea and rice beer are the only liquors used by the Japanese. Wines or distilled liquors are never seen amongst them; and they can hardly be persuaded to taste them, even when they are offered by the Dutch. Their only inebriating drink is sacki, which, being warmed in a common tea-kettle, is poured out into flat tea-cups made of lackered wood, and is in this manner drunk quite warm. Tea is drunk at all times of the day.

The dwelling-houses of the Japanese, whether public or private, are by no means to be compared to those in Europe, either for size or magnificence, being commonly low, generally consisting of one story, and built of wood, owing to the danger of earthquakes. Their apartments are small, but uncommonly neat and clean, and for the most part carefully and curiously furnished; the windows, doors, posts, and passages, are finely painted and varnished; and the ceilings neatly covered with gilt or silver-coloured paper, and embellished with flowers. They have few partition walls to divide the rooms from one another; but instead of these they use folding screens made of coloured or gilt paper, laid into wooden frames, which they can put on or remove at pleasure; and by this means they enlarge their rooms or make them narrower as best suits their fancy or convenience. These houses are built of cedar wood, of which there is great abundance in the country. The castles of the Japanese nobility are built either on great rivers or upon hills and rising grounds, and occupy a large space, consisting of three different fortresses or enclosures, which either cover or defend, or, if possible, encompass one another. Every enclosure is surrounded by a deep ditch, kept clean, and a thick strong wall built of stone or earth, with strong gates. The towns are mostly populous and well built; and the streets run straight forward, crossing at right angles. They have no fortifications. The two chief gates are shut every night. The villages along the highways are but thinly inhabited. The houses of the country people and husbandmen are small and poor, consisting of four low walls, covered with a thatched or shingled roof. "They have," says Kæmpfer, "many children and great poverty, and yet, with some small provision of rice, plants, and roots, they live content and happy." The temples dedicated to Buddha, or to other foreign idols, are far superior to all other buildings, for their great height, curious roofs, and numberless other beautiful ornaments. They are built of the best cedars and firs, and adorned with carved images of their idols. A fine altar stands in the middle of the temple, with one or more gilt idols on it, and a beautiful candlestick with sweet-scented candles burning before it. The best situations in the country are chosen for these temples; those which afford a fine view of the adjacent country, or are in the vicinity of a spring, a rivulet of clear water, or a wood with pleasant walks.

There are excellent roads throughout Japan, so broad and large, that two companies, however numerous, can pass each other with ease. The country is divided into seven large provinces, every one of which is bounded by a highway; and all the smaller provinces into which the country has been subdivided are in like manner bounded by highways, which all lead into the greater, as a common centre, and unite at Jedo, the capital of the kingdom and the residence of the emperor. These highways are divided into measured miles, so that a traveller, in whatever part of the empire he may be, can ascertain at a glance his exact distance from the imperial residence. Bridges are laid over all the large rivers after they emerge into the plains; but they have no means of crossing the mountainous streams, which roll with too rapid a current to admit the building of arches, except by fording them. They have not the art of throwing across a bridge from bank to bank, or of even constructing rope bridges, which is the common resource in such cases in all mountainous countries, in the South American Andes, and amongst the Himalaya Mountains. The number of travellers on the roads, according to Kæmpfer, is scarcely credible, owing chiefly, as he supposes, to the populousness of the country, and to the frequent journeys undertaken by the natives. The princes and lords, who are bound to go once a year to pay their court to the emperor, commonly travel with great pomp and magnificence, and with a train which fills up the road for some days, consisting, for the first order of princes, of twenty thousand men; of ten thousand for one of the second order; and thus diminishing according to the quality or revenues of the nobles. This retinue is made up of numerous troops of forerunners, harbingers, clerks, cooks, and other inferior officers, whose duty it is to provide lodgings and victuals for the approaching train. The prince's heavy baggage follows, suitably attended, and carried in small trunks packed on horses, each bearing a banner with the coat of arms and name of the possessor. Then follow the chief officers and noblemen attending the prince, with pikes, scimitars, bows and arrows, umbrellas, palanquins, led horses, and other marks of grandeur. The prince himself is carried in a palanquin by six or eight men clad in rich liveries, sixteen pages, who are persons of the first rank, and richly clad, walking before, and others by his side; whilst the rear of the procession is brought up by numerous domestics, grooms, footmen, pike-bearers, all in liveries, and by numbers of led horses. The whole train are clad in black silk; and they march in order, in profound silence, without any noise except what is occasioned by the trampling of horses and men. On the other hand, the etiquette is, that the pike-bearers, and the carriers of the palanquin, have their clothes tucked up above the waist; and thus their naked bodies are exposed to view, with only a small piece of cloth for the sake of decency. What appears still more odd and whimsical to a European is, that the pages, pike-bearers, umbrella and hat-bearers, chest-bearers, and footmen, affect a strange mimic march or dance when they pass through any remarkable town or borough, or by the train of another prince or lord. Every step they make they draw one foot up behind them as high as their back, and stretch out the arm on the opposite side as far as they can, "putting themselves in such a posture," says Kæmpfer, "as if they had a mind to swim through the air." The roads are besides crowded with numerous travellers, with pilgrims going on their annual visit to some holy temple, and with multitudes of beggars, in which character, indeed, many of the pilgrims travel. There are on all the roads idols of stone erected in honour of their gods, and other monstrous images and idols which occur on the highways in several places, at the turning in of sideways, near bridges, convents, temples, and other buildings. Coarse figures of these idols are also printed on entire or half sheets of paper, and pasted upon the gates of cities and villages, on wooden posts near bridges, and in other places on the highway most exposed to the traveller's view. But strangers are not expected to pay these idols any sort of homage. The Japanese are, contrary to the representations given of them, tolerant and liberal in matters of religion. The mission which was sent to Japan by Sir Stamford Raffles, and which Dr Ainslie accompanied, experienced this liberality in a manner that they by no means expected from the representations previously made to them. The English commissioner visited the great temple on the hills of Nagasaki, and was received with marked regard by the venerable patriarch, who entertained him sumptuously. On showing him round the courts of the temple, one of the English officers present, as mentioned by Dr Ainslie, heedlessly exclaimed in surprise, "Jesus Christus." The patriarch turning half round with a placid smile, bowed significantly, as if intimating that he was perfectly aware of the difference of their respective creeds; and they parted mutual friends, with a hearty shake of the hands.

For the accommodation of travellers, there is in all the chief villages and hamlets a post-house belonging to the lord of the place, where are procured horses, porters, footmen, or whatever else may be wanting for their journey, at settled prices. Travellers of all ranks and qualities resort to these post-houses, which lie at about one and a half to four miles distance from each other. They appear to have no carriages, but either travel on foot or on horseback, or along the coast by sea. At these post-houses messengers are walking day and night, in order to carry the letters, edicts, and proclamations of the emperor and the princes of the empire, which they convey from one post-house to another with all speed. Two messengers are always employed on these occasions, that in case any accident should befal the one, the other may forward the despatches, which are kept in a varnished box bearing the arms of the emperor, to the next stage; and all travellers, and even princes of the empire and their retinues, must retire out of the way in order to give a free passage to these messengers.

The Japanese are represented as a vigorous people, both in their bodily and mental habits. They are well made, active, free, and easy in their motions. The men are of the middling size, and in general not very corpulent. They are, says Thunberg, of a yellowish colour all over, sometimes bordering on brown, and sometimes inclining to white. The labouring classes, who, in summer, when they are at work, lay bare the upper part of their bodies, are sun-burnt, and consequently brown. Their features are masculine and perfectly European, with the exception of the small lengthened Tartar eye, which almost universally prevails, and is the only feature of resemblance between them and the Chinese. Dr Ainslie gives rather a different account of their complexion from Thunberg. He represents them as perfectly fair, and indeed blooming; though this seems to apply chiefly to the women, who, he says, are equally fair with Europeans, and have the bloom of health more generally prevalent amongst them than is usually found in Europe. Thunberg also mentions that ladies of distinction, who seldom go out in the open air without being covered, are perfectly white. Their eyes are generally dark-brown, or rather black; and the deep furrow which the eyelids form in the great angle of the eye discriminates the Japanese

Japan. from other nations. They have generally large heads and short necks, with black, thick, and shining hair, from the oil which they put upon it. Their noses are rather thick and short, though by no means flat.

The dress of the Japanese is a complete uniform, from the monarch down to the lowest of his subjects; it is the same in both sexes, and has been unchanged for the space of more than two thousand years. It consists everywhere of long and wide gowns, one or more of which is worn by all ranks. The dress of the poor is distinguished from that of the rich only in the materials being made of cotton instead of the finest silken stuffs, which are frequently flowered, and sometimes interwoven with figures in gold. They reach down to the feet, and are frequently worn by women of quality with a train. Travellers, soldiers, and labouring people, either tuck them up, or wear them so short that they only reach to the knees. These gowns are fastened about the waist with a belt, which is of such a length as to go twice round the body with a large knot and rose, which is worn by the married women before, and by the single behind. To this belt the men fasten their sabre, fan, tobacco-pipe and pouch, and medicine-box. The gowns are rounded off about the neck; they are open before, and display the bare bosom. The sleeves are ill shaped and wide, and sewed together in front so as to form a bag at the bottom, in which they put their hands in cold weather, or use it as a pocket to hold their papers and other things. They wear, besides, breeches, which are more like a petticoat than breeches, being sewed between the legs, and left open at the sides for about two thirds of their length. There is, besides, a dress of ceremony, which is worn on the outside, over the gowns. It consists of two pieces; the undermost the above-described breeches, which are generally made of a blue stuff, printed with white flowers; the uppermost is a frock, not unlike a half gown. Besides silk and cotton, they use a kind of linen, which is manufactured from a certain species of nettles. The silk worn by the richer classes far exceeds in tenuity and fineness the silks either of India or Europe. The shoes are the most indifferent part of the Japanese dress.

Of the population of Japan no accurate account has ever been obtained, and all our information on this subject is merely conjectural. Every spot is cultivated even to the mountain tops; and all Europeans who have ever visited Japan concur in representing it as extensively populous. On these grounds, and taking into account also the area of the country, it is supposed that the population cannot be less than fifteen or twenty millions. Sir Stamford Raffles' estimate, from the accounts brought to him by Dr Ainslie, is twenty-five millions.

History. It was from the Portuguese that the nations of Europe received the earliest accounts of the Japanese islands. The mariners of Portugal first adventured on the Indian Ocean in the year 1497, and they long carried on a lucrative commerce in the ports of the East. The conquest of Goa by Albuquerque, in the year 1510, laid the foundation of their future power; and from that time they pursued with success their conquests and discoveries in the East, and carried on an extensive trade. In 1542 one of their ships was forced by a storm on the yet unknown islands of Japan; and afterwards a ship, richly freighted, sailed every two years for one of their ports. In 1549, a young Japanese, who had fled to Goa, and there embraced the Christian faith and was baptized, held out to the Portuguese the most sanguine prospects of gain from a trade to Japan, and even gave hopes to the Jesuits of converting the people to the Christian faith. These pious fathers were not slow to profit by the hints of their new proselyte; and, with a view to a permanent establishment in Japan, the young Japanese was sent back to his own country on board a Portuguese ship, accompanied by several of the Jesuits, and by St Francis Xavier, the head of the mission. At that time no restraint was imposed on the intercourse of the Japanese with foreign states; the Portuguese were therefore allowed to trade with whatever parts of the empire they thought fit, and were much caressed by several of the princes, and invited to settle within their territories. The princes and nobles of the country vied with each other to obtain the favour of the strangers, and a most lucrative trade was carried on in European and Indian commodities, such as raw silk, fine silk stuffs, drugs, wines, medicines, and a great variety of other productions, both natural and artificial, which were exchanged for gold and other produce or manufactures of the country. By this traffic the merchants were enriched, and in a few years carried off a large amount of treasure, though not perhaps three hundred tons of gold every year, as Kæmpfer says, with a boldness of assertion not very consistent with his usual caution and accuracy. The Jesuit missionaries on their part were not idle. They laboured diligently in their vocation, and they commended the doctrines of the gospel by their modest and virtuous life, and by their disinterested benevolence to the sick and the poor; whilst the pomp and majesty of the Catholic service arrested the attention and affected the senses of the Japanese. The first difficulties being surmounted, converts began to flow from all quarters; and many of the princes and nobles, being converted to the new doctrines, were baptized, and agreed to send an embassy to Pope Gregory XIII. with letters and presents, assuring him of their devotion to the Christian faith. In this manner the Portuguese prospered in all their concerns, both spiritual and temporal; and fresh supplies of missionaries and merchants from Manilla, Macao, and Goa, daily flocked to this profitable mart of religion as well as of trade. But the fair prospect was at last overcast by the darkest clouds of bigotry and persecution; the Christian faith, which had been so successfully planted and propagated, was rooted up and completely extirpated; and, instead of the free intercourse formerly allowed with all nations, commerce was placed under the most severe restraints, and was finally restricted to one part, that of Nagasaki, and to two nations, the Chinese and the Dutch.

This great revolution originated in various causes. The great prosperity of the Portuguese appears to have filled them with insolence and pride; the priests and others no longer walked on foot, but, being carried about in stately chairs, mimicked in this and other matters the pomp of the pope and cardinals at Rome; whilst the Japanese priests, and others who profited by the prevailing religion, were displeased at the alterations which had been introduced, being fearful of the injurious consequences to their interest, and contrived to instil into the emperor a jealousy of the new sect. It is related of one of the Portuguese priests, that having met on the road one of the counsellors of state, the haughty prelate would not allow his chair to stop, according to the fashion of the country, in order to pay respects to the great man, but commanded his men to pass on without even showing him common marks of civility. This neglect inspired the nobleman with an unconquerable hatred of the Portuguese; and, in an interview with the emperor, he gave such an odious picture of the insolence, pride, and vanity of the whole nation, as raised the emperor's indignation to the highest pitch. In 1586 a proclamation was issued by the emperor, forbidding any of his subjects, under pain of death, to embrace the Christian religion; and the same year began the persecution, which is the most sanguinary every recorded in any age or country. Several converts were executed for disobeying the imperial commands; and, according to the letters of the Jesuits, more than twenty thousand persons suffered death in the year 1590. Still the converts increased, for in 1591 and 1592, after all the churches had been shut up, twelve thousand new converts were made. In 1597 a new persecution was raised against the Christians, and twenty-six persons, including Jesuits, and several of the Franciscan fathers, were executed on the cross. It happened that the crown was about this period usurped by an adventurer of the name of Ijejas, whose doubtful title conspired with his fears and jealousy of the Christians to render him a cruel persecutor. He issued a proclamation, strictly forbidding the Portuguese missionaries any longer to preach the Christian faith; and directing all the governors, princes, and lords in the several provinces of the empire, to induce their subjects, either by force or persuasion, to renounce the Christian and adopt their former faith. The monks and priests already in the country were banished, and the Portuguese were strictly forbidden to bring any more of them to Japan. These orders, however, were not at first rigidly enforced. The Jesuits could not be persuaded to quit a country where their labours had been so successful in gaining both wealth and proselytes; and fresh supplies of ecclesiastics were still brought from the Portuguese settlements. But the rashness of the Franciscan friars, who were ambassadors at the imperial court, and who insisted on openly preaching in the streets of Miaco, and built a chapel, in direct opposition to the edict that had been published, hastened the total ruin of the Portuguese interests in Japan. Many were also disgusted by their ambition and covetousness, when they saw that these spiritual fathers aimed fully as much at the possession of money and lands as the salvation of souls. From all these various causes a dreadful persecution was commenced against the Christians, who were put to death without mercy wherever they were found. This persecution lasted forty years, and, after the cruel butchery of thousands, ended at last in the total extirpation of the Christian faith, the ruin of the trade, and the final expulsion of the Portuguese and Castillians from Japan. It was long before this last severe measure was resolved on, as the Japanese, however intolerant in matters of religion, were still anxious to obtain the commodities of Europe; and they appointed the island of Desima, in the harbour of Nagasaki, as the residence of the Portuguese merchants. But the Dutch, who some time prior to the year 1600 had extended their navigation to these seas, were now the zealous competitors of the Portuguese and Spaniards for the eastern trade; and the two nations being at this time at war, were not scrupulous in using the most unworthy arts to supplant each other in the good opinion of the Japanese. It is asserted by Kæmpfer that the Portuguese invented the most malicious stories in order to blacken the character of the Dutch, representing them as rebels and pirates, and altogether unworthy of trust. The Dutch on their part resorted to the same artifices, and with some success. It is stated, that in a Portuguese ship which was taken by the Dutch, they found letters to the king of Portugal, written by one Captain Moro, a Japanese by birth, and a Christian proselyte, containing the scheme of a conspiracy for overthrowing the existing government. The Dutch were not slow to profit by this precious discovery. They immediately communicated the letters to the Japanese authorities. Captain Moro was arrested, and, notwithstanding the most earnest protestations of innocence, was burned alive. In proof of the Portuguese treason, intercepted letters were shown, disclosing, as was alleged, the whole plot against the emperor's life and throne; the want the conspirators stood in of ships and soldiers, which were expected from Portugal; the names of the Japanese princes concerned in the conspiracy; and various other particulars, which were received as convincing evidence of this extensive treason. On this discovery the edict was forthwith issued, in 1637, forbidding, on pain of death, all intercourse with foreigners; prohibiting, under severe penalties, the propagation of the Christian religion, and the purchase of any article by a native of Japan from a stranger; banishing all the Portuguese to Macao, and shutting out for ever all other nations from the Japanese islands.

The Portuguese and Spaniards still lingered, in hopes of mitigation of this severe decree; but the Japanese court, being assured by the Dutch that they would supply them with European goods, proceeded to a rigorous execution of the edict, and from this period the trade of Japan has been entirely confined to the Dutch. An attempt to renew the trade, by sending an embassy from Macao, entirely failed, the ship being seized, and the crew executed, with the exception of twelve, who were sent back to their countrymen with an account of this tragical result, but who perished on their way home. It appears to have been chiefly by the intrigues of the Dutch that this great revolution was brought about. The persecutions to which the Portuguese were exposed might naturally enough have engaged them in plots against the Japanese government; but the whole story rests on the evidence of the Dutch, the rivals of the Portuguese, whom they were anxious to ruin, without much scrupling at the means of attaining their end; and in revealing the plot which produced an edict for the extirpation of the Christian faith, and the massacre and banishment of thousands of Europeans, it is plain that they were actuated by the basest motives.

By the ruin and expulsion of the Castillians and Portuguese from Japan, the Dutch acquired the monopoly of the trade, which they were so intent on securing that they cultivated the favour of the Japanese monarch by the most servile and criminal compliances. Their conduct was indeed most degrading. They made presents to the imperial court, of all the rare animals they could collect from the most remote quarters of the world; and they complied with all the commands of the emperor, however despotic or unjust. They were obliged, in 1638, to abolish their factory on the island of Firando, for no other reason but because it was built of hewn stones, and finer than the other buildings of the country, and because the Christian era was engraved on the front; and the part which they acted in the massacre of the Japanese Christians at Simabara leaves a deep stain on the national character, proving as it does that the love of gain had extinguished every sentiment of humanity in the breasts of these traders. The Japanese Christians, by the unparalleled cruelties and torments to which they were exposed, were driven to despair; and they had retired, to the number of forty thousand, to a fortified place in the neighbourhood of Simabara, where they were resolved to defend themselves to the last extremity. The emperor requested the aid of the Dutch in the siege of this last stronghold, in the massacre of these Christians, and in the utter extirpation of the Christian name in Japan. This aid was at once afforded. A Dutch vessel of war was sent to batter the town, and a breach was made in the defences of these unfortunate refugees, through which their enemies entered and perpetrated a massacre unparalleled for enormity even in the blood-stained annals of the East. According to the information received by Dr Ainslie from the Japanese, they were prompted to this massacre by European intrigue; and the alacrity of the Dutch in lending their aid, joined to their hatred of the Portuguese, concurs to fix on them a deep share in this shocking atrocity. But they were far from recommending themselves to the Japanese by their treacherous conduct. "By this submissive readiness," says Kæmpfer, "to assist the emperor in the execution of his designs with regard to the final destruction of Christianity in his dominions, 'tis true indeed that we stood our ground so far as to maintain ourselves in the country, and to be permitted to carry on our trade, although the court had then some thoughts of a total exclusion of all foreigners whatever. But many generous and noble persons, at court and in the empire, judged quite otherwise of our conduct, and not too favourably for the credit we had thereby endeavoured to gain. It seemed to them inconsistent with reason that the Dutch should ever be expected to be sincerely faithful to a foreign monarch, and one, too, whom they looked upon as a heathen prince, whilst they showed so much forwardness to assist him in the destruction of a people with whom they otherwise agreed in the most essential parts of their faith, as the Japanese had been informed by the Portuguese and Manilhese fathers, and to sacrifice to their own worldly interest those who followed Christ the very same way, and entered the kingdom of heaven through the same gate; expressions which I have often heard the natives make use of when the conversation happened to turn upon this subject. In short, our humble, complaisant, and obliging conduct notwithstanding, we were so far from bringing this proud and jealous nation to any greater confidence, or more intimate friendship, that, on the contrary, their jealousy and mistrust seemed to increase in proportion to the many convincing proofs of sincerity and faithfulness we gave them; and that the better we deserved of them, the more they seemed to hate and despise us, till at last, in the year 1641, soon after the total expulsion of the Portuguese, orders were sent us to quit our old factory at Firando, to exchange the protection of a good and indulgent prince for the severe and strict government of Nagasaki, and under a very narrow inspection to confine ourselves within that small island, I should rather say prison, which was built for the Portuguese." In this island or prison, 600 feet long by 240 broad, the Dutch continue to carry on their trade, where they are guarded like thieves or pirates, and placed under the most degrading restrictions. Kæmpfer gives a minute account of the guards that are placed over them, of the vigilance with which they are watched, of the daily musters that are made to see that none is amissing, of the extraordinary precautions employed to prevent the introduction of contraband goods, and of the sure penalty of death that follows the violation of the law. He gives an account of the punishment of two men, Japanese, who were detected with camphor concealed about their persons, which they had purchased from the Dutch, and who for this crime had their heads struck off by the common executioner; a deputy from the Dutch establishment being expected to attend at the execution, and to witness, for the instruction of himself and his companions, this wholesome example of severity. On one occasion, also, he relates that a Dutch sailor had thrown himself over board, and that when he did not appear at the daily muster the Japanese were all in despair, being terrified that it might be a Roman Catholic priest, and that he might have escaped into the country. "All the officers," he observes, "ran about scratching their heads, and behaving themselves as if they had lost their senses; and some of the soldiers in the guard-ships were already preparing to rip open their bellies, before superior orders could compel them to answer for their carelessness and neglect of their duty." It was not till the man's body was got up from the bottom of the sea that this alarm began to subside.

The moment the Dutch vessels are seen steering for the harbour by the spy-guards with their glasses, the system of vigilance begins. The ship is boarded by three persons from the Dutch factory, and the public interpreter, and the deputies from the governor, demand forthwith the list of the cargo and crew, also the letters on board, which are carried to Nagasaki, where they are examined by the governors. On entering the harbour, two guard-boats, with a number of soldiers on board, are placed on each side of her, and continued in their position, the guards being regularly changed till her departure. All arms, namely, guns, cutlasses, swords, and also the ship's stock of gunpowder, are given into the custody of the proper officers. The persons and trunks of the sailors are all searched with the utmost strictness, also every corner of the vessel; and the different packages are rigidly examined. All the approaches to the island in which the Dutch are settled are strictly guarded, both day and night, by officers appointed for the purpose. There is a company or corporation of interpreters, amounting to one hundred and sixty, who also do the duty of spies; and during the time of the annual sale the vigilance of all these functionaries is redoubled. Those who come to trade with the Dutch must submit to a strict search of their persons before they are admitted within the gates leading to their residence. No letters can either be sent or received unless they are previously entered in a register book, and a copy left with the governors.

The Chinese, who are admitted to trade along with the Dutch, are subjected to similar restrictions. They formerly carried on a free intercourse with Japan; but it was intimated to the Japanese that the Jesuits, after their expulsion from the country, had experienced a most friendly reception in China, and it was discovered that several of their books had been brought over by the Chinese and privately sold. This, together with the vast influx of the Chinese into Japan, raised the jealousy of the emperor and the court, and the Chinese were finally laid under the same restraints as the Dutch.

The goods chiefly imported into Japan are raw silk from China, all sorts of silk and woollen stuffs, coarse cotton stuffs, woollen cloth from Europe, hides raw and tanned, sugar, coffee, spices of all kinds, quicksilver, cinnabar, saffron, lead, saltpetre, borax, musk, gums, coral, amber, various articles of glass, and iron, lead, tin. The returns are chiefly made in copper, and along with it camphor, lackered ware, painted paper, and other articles of comparatively little moment. The trade of the Dutch and the Chinese with Japan was formerly very extensive. From the year 1611 to the year 1671 the speculations of the former were unrestricted, and their profits were enormous. According to the account of Kæmpfer, the Dutch gradually fell into discredit with the Japanese; their commerce was curtailed, they were subjected to ignominious treatment, their profits were diminished, and the trade is now confined to two annual ships, which sail from the port of Batavia. The Chinese send annually ten junks to the port of Nagasaki, the only port which is open to foreigners.

In 1814, when the island of Java was in possession of the British, Sir Stamford Raffles, the governor, distinguished on all occasions by his enlightened zeal for the interests of science and of social improvement, was deeply impressed with the importance of opening a commercial intercourse with the Japanese, and of acquiring for Britain a participation in the trade hitherto monopolised by the Dutch. The Japanese islands, containing, according to his estimate, about twenty-five millions of inhabitants, who require woollens, hardware, iron manufactures, and glass, besides many other articles, might, he justly conceived, afford a very extensive market for British goods. With this view, when the time arrived for the annual visit of the Dutch to Japan, he joined two other gentlemen in the mission, one of whom was Dr Ainslie, for the purpose of obtaining accurate information respecting the Japanese, and the Dutch establishment in Japan. He confirms all the previous accounts that had been received of the narrow and exclusive policy of the government, in consequence of which few op-

Japanning. portunities were afforded of a free communication with the natives. The commissioners, however, who were sent to Japan by Sir Stamford Raffles, state that the character of the Japanese had been greatly misrepresented by the Dutch for their own selfish purposes, and through fear of being interfered with by any other of the European states. So far from being a bigoted and intolerant race, as they are represented, they appeared to be remarkable for frankness of manner and disposition, for intelligence and the spirit of inquiry; and, in regard to religion or superstitious prejudices, to be perfectly inoffensive. The British commissioners were strongly of opinion that the commercial restrictions did not so much arise from the limitations or from the laws of the Japanese, as from the constitution of the Dutch factory. It is the interest of the resident and other functionaries to narrow the trade, that they may secure a larger profit for themselves; and, living at a distance from control, with a limited salary, they are compelled to scramble for every petty advantage to themselves, to the neglect of the general interests and prosperity of trade. From the degraded state of the Dutch factory, and the corruptions which prevail, the national character of this commercial people is lowered in the eyes of the Japanese, at whose hands they endure every species of humiliation. They prostrate themselves not only to the emperor, but also to the inferior chiefs, for which they are despised by the Japanese, as well as for all the other mean compliances which they submit to, rather than run the risk of sacrificing the trade. It was indeed intimated by the Japanese interpreters to Dr Ainslie, that the Dutch were the secret instigators of the massacre of the Christians at Simabara, and it is certain that they lent their active aid in that bloody transaction. The English commissioners were most courteously received in Japan; the people evinced the most earnest desire to communicate with them; their presents were even graciously received by the emperor; and, from this auspicious commencement, the most favourable hopes were entertained of a closer and more friendly intercourse with this singular people. But the surrender of Java to the Dutch put an end to all these expectations of extended trade; and the intercourse with Japan has since been continued on its former footing, all competitors having been, as heretofore, rigidly excluded.

Various attempts have been made by the Russians to open an intercourse with these islands, from their establishments along the eastern coast of Asia. But all friendly overtures with a view to a commercial intercourse have been decidedly rejected. In 1792 a deputation arrived from Japan at Okhotzk, requesting the aid of the Russians to extricate some unfortunate Japanese who had been thrown upon the desolate island of Oonalaska. The Russians were extremely ready in lending their aid in the cause of humanity, and the Japanese expressed the utmost gratitude for the services which they rendered them. The opportunity was deemed favourable for renewing the offer of commercial intercourse, and Captain Laxmann was sent, by orders of the empress, to that part of the coast of Jesso or Matsmai which is occupied by the Japanese. He was kindly received, and loaded with presents; but all commercial intercourse was steadily rejected. In 1814 Count Krensenstern, despatched to Japan on a similar errand, met with no better success. He was peremptorily told, by orders of the emperor, that his subjects traded only with the Dutch and the Chinese; and from the moment that he and his attendants arrived, they were exposed, as has already been related, to every possible ignominy, through the influence of the Dutch factory, jealous of competition; and they were finally requested to return to their own country, as they valued their lives, and never to come back. Since this time Captain Golownin, who was enticed on shore and detained in a severe captivity by the Japanese, reports that they are extremely jealous of the ascendency both of the Russians and of the English in the East, from the establishments of the Russians along the northern, and of the English along the southern coasts of Asia. These jealousies, there is every reason to suppose, are fostered by the Dutch, who alone have access to the Japanese, and who have even persuaded them that the Europeans are intent on adding Japan to the other extensive conquests which they have acquired in the East. At present, therefore, there is no prospect of any change in the exclusive policy of this singular people. They are even more rigid in their maxims of exclusion than the Chinese, who, through the free port of Canton, trade indiscriminately with all nations. But the Japanese confine the privilege of commerce to one port and to two nations, who either cannot or do not find it their interest to supply them with foreign produce to the extent which would be required if the existing restrictions were abolished. The cession of Java to the Dutch at the peace of 1814 is deeply to be regretted on this account, that it closed the door against all further communication of the British with Japan, and for ever frustrated the judicious and enlightened plans of Sir Stamford Raffles for promoting a free intercourse and a more extended trade with these islands. (F.)

JAPANNING, the art of varnishing and drawing figures on wood, after the manner of the Japanese, from whom it takes its name. The substances which admit of being japanned are almost every kind that are dry and rigid, or not too flexible; as wood, metals, leather, and prepared paper. The practice of japanning goods has varied from time to time. The following are some of the methods practised at present.

Japanning of cast and sheet iron black. Mix up some vegetable black with naphtha or spirit of turpentine, and let it sour for a night; then add as much japan as will not take away the body of the black. After the article has been freed from rust, coat it with this, and put it into the stove. When dry, let it be coated with japan; two coats are sufficient if the japan be rich or old. If the article is intended to be polished, another coat or two may be given, according to the surface of the article; and let it be gently cooled between each coat.

Polishing. To polish the above, take a piece of close-grained pumice-stone, ground down to a smooth and perfectly level surface, and with this slightly rub down all the knots. When this is effected, put the article into the stove till the parts which have been rubbed are hardened. Then take a piece of woollen cloth, stuffed with something of the same description, to the size of a small hand mallet, which japanners call a polishing bob; wet it through with water, then dip it amongst pumice-stone which has been sifted through muslin, and rub the whole surface till it is smooth. Sponge it clean with water when dry. The surface is then made perfectly smooth and fine by being rubbed with a piece of cloth similar to that just mentioned, and ground rotten-stone moistened with water. It is then wiped clean with soft silk; and, when dry, hard powdered rotten-stone is rubbed upon it with the points of the fingers, lengthways, when it receives a beautiful gloss. To preserve the lustre, sprinkle a small quantity of sweet oil and water over the whole, then smartly with both hands clean off the oil and water. This will produce a permanent and brilliant glossy black. If the cast or sheet iron is not ground, there is no use for the first coat of black, as the same coats of japan answer the purpose perfectly well.

Japanning.

In japanning tin, care must be taken to deprive the article of any rosin or grease. It then receives one coat of black and two coats of japan, as in the case of cast or sheet iron. If it has to be polished previously to being coated, it is rubbed smooth lengthways with a piece of wool-comber's card, or coarse sand-paper. This will greatly aid the polisher, and in some instances may save a coat of japan. The article is then polished and oiled as before described.

Clean the tin as before mentioned, and give it one coat of japan. Let it then be put into the stove, and when dry give it another. If a dark brown is required, it is subjected to a strong heat; and if a light brown, a coating and a gentle heat only is necessary. Care must be taken that each coat is well settled or stiffened in the air, by turning it upside down to keep it from flowing all one way, before putting it in the stove.

Grind some Venetian red in spirit of turpentine very fine, to which add three parts of mixing varnish with one part of japan, that is, as much as will not take away the body of the red. Coat the article, and put it into the stove till it dry. Then give it one coat of japan pretty fluid, and let it settle in the air, as mentioned above. Put it again into the stove, and when dry it will appear of a fine brown colour. All metals may be japanned in this way, especially old tin ware. If a polish is required, use common vermilion instead of Venetian red, as it will require more coats. Another brown, commonly called chocolate, may be produced by using purple brown in the same way.

In japanning wood in the same way as metal, it ought to be dried or seasoned well in the stove before coating. A black is obtained by using the same black as that already mentioned. After the article has been dried in the stove and taken out, it is coated with japan; and this is repeated until the surface becomes smooth. Care must be taken not to let the article cool between the periods of each successive application of the japan, else the air may insinuate itself into the pores of the wood, and cause it to blister when put into the stove again. The article made or turned must be in one piece.

In japanning table tops, the best Spanish mahogany, plained and smoothed with sand-paper, must be used. First put it in the stove between two plates of iron, with a sufficient weight on it to keep it from casting or warping, till it be properly seasoned. Take it out and coat it with black as above mentioned. Afterwards put it into the stove to dry. Then coat it with japan until it has a flowing appearance. Should it blister between the coatings, rub the blisters down with fine sand or glass-paper. After the last coat has been applied, allow it to become perfectly hardened, and then polish it in the same way as metal is polished. This method is not generally known or practised, a prejudice existing that it will not stand the heat; but Spanish mahogany, three fourths of an inch thick, will stand the same heat as tin.

Small fire-screens made of plain-tree and other kinds of wood may be japanned in the same manner; but as they are done on both sides, it requires a frame made of tin, tapered inwards, so that the screen may rest gently on the edges of it. Flat articles, which cannot stand the necessary temperature, are japanned in the following manner. Grind fine some ivory-black with turpentine, then add two parts of japan and two parts of drying copal varnish; and after the wood has been well dried, coat it over three times. When it is dry, smooth it down with wet rag and ground pumice-stone. The smoothing being finished, take extra quick copal varnish, tinged with ivory-black, and give the article two coats. When these are hardened it may be polished. If great care be taken in laying on the varnish, polishing may not be necessary.

Coloured grounds on wood. White.

To a white lead ground in turpentine add one part of drying copal varnish, and mix them together. Coat the wood till the pores be filled up, and then rub it down as before described. Then take flake-white ground in turpentine, and add to it three parts of fine dial varnish; strain it through fine muslin, and let it stand for five or six hours; after which, coat the wood over twice, and let the first coat be properly hard before the other is applied. When sufficiently hardened, take a piece of fine flannel dipped in rotten-stone ground in water, and rub it till smooth, when it is rendered fit for working on. But if it is to be finished in the white, let it be rubbed all over with a mixture of sweet oil and flour, and then dusted with dry flour, which is afterwards wiped clean off with both hands, leaving a fine glossy surface.

Yellow.

The yellow ground may be filled up in the same way as the above with the lead. When it is filled up, take chrome-yellow ground in turpentine, and add three parts of fine drying copal varnish; strain this, and coat the article with it, as in the above case, and varnish and polish it in a similar manner.

Red.

Take common vermilion ground in turpentine, to which add one part of quick-mixing varnish. Fill up the ground with this, and then take Chinese vermilion ground in fine drying oil, thick, adding to it a small quantity of fine mixing varnish, to make it free in working. With this preparation the article is twice thinly coated, which method is preferable to laying on only one thick coat. When dry, it will be fit for working on. But if it is intended to be polished, give it two coats of fine quick-polishing varnish, and let the first coat be very hard before it receives the second. After it is properly hardened, take a woollen rag dipped in ground pumice-stone and water, and rub the ground all over. When it is smooth, take a flannel rag dipped in ground rotten-stone, and finish it, as in the case of the white.

Blue.

Fill up the blue ground in the same manner as the white is filled up; and a little Prussian blue may be added to it. When filled up, Prussian blue and white lead are ground by themselves upon the same stone, and afterwards mixed together in proportions varying according to the shade required. The after-process for polishing is the same as that already described.

Green.

Fill the green ground as in the case of the white, adding lamp-black to make it of a lead colour, the quantity employed being in proportion to the shade required. When filled up and smoothed, take emerald-green ground in turpentine, and add a small quantity of mixing varnish to it, so that the green may be flat, for it will require three coats, as the green has a very little body. It is then smoothed and rendered fit for working on. If a dark hue is wanted, take Brunswick green, which may be made lighter by adding a little chrome-yellow; or darker, by adding Prussian blue and black. This green is more easily produced than any other. Varnish and polish the article as before described.

Purple.

Take white lead ground in turpentine, and add crimson-lake and Prussian blue, according to the shade wanted. The article is then coated, varnished, and polished, in the same way as the red. All the above grounds may be enriched by giving each a coat of thin primitive colours ground in turpentine, and mixed up with fine clear mixing varnish. These are crimson-lake for red, yellow-lake for yellow, Prussian blue for blue, verdigris for green, and lake and blue for purple.

To produce damask grounds for white, when the ground is fit for working on, take fine dial varnish for size, so that it may not discolour the ground, and size the device. Let it stand till it slightly attaches itself to the finger; then take a piece of shamoy leather, dip it in silver powder, and shade the device with it, when it will appear like damask.

Japanning.

Red and crimson damask.

For obtaining red or crimson, after the ground has been smoothed with the common vermilion, take japanners' gold size, thin, and size the device; when it adheres to the finger, take orange-bronze and shade it as above. This being dry, coat it with crimson-lake ground in turpentine and mixed with fine polishing varnish; polish it as usual, and a rich damask ground will appear.

Yellow damask.

This ground must be a very light yellow. Use size and silver powder, the same as in the case of the white; coat it with yellow-lake ground in turpentine and mixed with polishing varnish; coating, varnishing, and polishing it as usual.

Blue.

Make the ground a very light blue, almost approaching to white; use the size and silver as in the above case; take Prussian blue ground in turpentine and mixed with polishing varnish, and coat it to the shade required, then varnish and polish it as usual.

Green.

Make a light bluish-green with verdigris and white lead ground, use size and silver as in the case of the white, then take verdigris ground in terpentine, and mix it with slow-drying varnish, to prevent it from cracking, as the verdigris is very brittle; coat it to the shade wanted, and varnish and polish it as usual.

Purple.

Make a ground of crimson lake and Prussian blue mixed with white lead, very light; then take lake and blue ground in turpentine and mixed with polishing varnish; coat it to the shade required, size and silver it as in the case of white, and varnish and polish it as usual.

Beautiful grounds are produced with the silver powder; and devices on black grounds with either of the above colours, which greatly enrich the appearance of the deep or pale gold ornaments that are wrought upon then.

All the above coloured grounds may be produced on metals in the same way, with the exception of the white. In filling up metals, take Venetian red ground in turpentine or tar spirits, add as much japan as will give it body enough, so as not to crack, and afterwards coat the article till it is filled up; then smooth it down with lump pumice-stone. Put it into the stove till dry every time it is coated, then lay on the ground colour as before mentioned.

With regard to sizing and gilding on japan grounds, take the gloss off the part that is to be worked on, by which means the size will be better seen. In ornamenting any article, as, for instance, a tea-tray, with various golds, bronze, and colour, proceed thus: After tracing or drawing out the ornaments, size the parts for your deep gold first, and then gild them, the parts for the pale gold being also gilt; and care must be taken that the size has but a slight adhesive feel before the gold is put on. If bronze shaded is introduced, size the part first, and then take a hair pencil and dip it into the bronze or gold powder gently; then rub the sized part, and it will produce a soft shade. If it is to be solid bronze, let it be nearly dry; rub the sized part gently over with a piece of shamoy leather dipped in bronze, then warm the tray, and rub the part over smartly, when it will appear solid with a metallic lustre. After all is gilt and bronzed, take a common pen and etch up all the finer parts of the ornament with it; but for the stronger parts take a fine camel-hair pencil dipped in black, to open up the ornament. The gold may be shaded with terre senna, and then put into the stove till dry, when it may be varnished and polished in the usual way.

In putting on raised work, take Chinese vermilion two parts, and white lead two parts; mix them thick together with turpentine, adding a small quantity of japan so as to make it adhere to the ground. Then take a long hair pencil and dip it amongst the raising, keeping the pencil upright so as to feed the point. Although the raising appear flat or dull, it will take a bright polish by rubbing it with the finger, after which it is sized and gilt.

Japetus || Japheth.

In imitating Japanese or Chinese, this must be done on gloss or polished ground. As this kind of work is not varnished, a little oil-colour may be mixed with the gold size, such as white lead or chrome-yellow, which will enable the fine lines to be better seen, and make the work more closely resemble gilding.

In painting on japan work, either oil or varnish colour may be used. The varnish colour looks clearest, and is most showy, but it requires great practice to blend the colours so as to appear soft; oil-colour is at present that most frequently used.

In varnishing white wood-work, or work covered with paper, take sheep-skin size in a liquid state, dip into it a camel-hair flat brush, and come over the work swiftly with it, so as not to wash up the painting. When this is dry, take hard white spirit varnish and a camel-hair flat brush, and coat the work over smartly. It will appear whitish at first, but it will become clear as it dries. After it has received four coats, let it stand for a day, until small cracks appear all over it. Rub the gloss off the work, or any knots, with the dry fingers, and then wipe it clean; after which give three or four coats more, when the varnish will appear full and flowing. Allow it to stand for a day or two, then take a piece of woollen cloth wet with water, dip it in ground pumice-stone, and smooth down the work with it, and then wipe it clean. After this take a piece of woollen cloth and dip it in rotten-stone ground in sweet oil, with which rub the work till a gloss appears. After wiping it, dip a piece of fine flannel in sweet oil mixed with flour, and rub the work smartly; powder it with dry flour, then rub it quickly off with the palms of the hands, and a brilliant gloss will appear.

In japanning paper after it comes out of the dip-stove, it must be coated till a full flowing body of japan is produced. In polishing the above, care must be taken that the ground is not overheated in the rubbing. If it be brought up with amber varnish, it must stand till it be thoroughly cool, otherwise the attraction of the ground will draw the size out of the pencil before the work can be executed. As black japan is generally the colour that paper-grounds are filled up with, it greatly depends on the japan or varnish being rich or old, as either will produce a good gloss to the number of coats given. For any other colour that is required, rub down the above ground smooth; for the first coat let it be white, but tinged a little with the colour wanted, unless it be marone. The first coat must be a light-olive colour smoothed down, thinly coated with crimson lake; if a dark marone, purple-lake is the pigment employed. The best polishing varnish ought to be used in the finishing. Paper trays are brought up in boards, sheet above sheet, with paste, to the thickness required, with the exception of the edges, which are done upon iron moulds, and then taken off, planed, glued, and nailed together, like a piece of wood. With regard to Bristol board, or any other paper, it is japanned in the usual manner, with a first coat of sheep-skin size to make it bear out.

JAPETUS, a son of Cœlus and Terra, who married Asia, Asope, Theonis, or Clymene, and had four sons, Atlas, Menœtius, Prometheus, and Epimetheus. He was thus considered as the author of the Hellenic race. (Apollodor. i. 1, 2; Diodor. v. 66, 67; Hesiod, *Theog.* 134. Iapetionides, a son of Japetus; Atlas, Ovid. *Met.* iv. 631). He is supposed to be the same as Japheth, the son of Noah.

JAPHETH, the son of Noah. His descendants possessed all Europe and the islands in the Mediterranean, as well those which belong to Europe, as those which depend on Asia. They had all Asia Minor, and the northern parts of Asia above the sources of the Tigris and Euphrates. Noah, when he blessed Japheth, said to him, "God shall enlarge Japheth, and he shall dwell in the tents of Shem; and Canaan shall be his servant." This blessing of Noah is supposed to have been accomplished when the Greeks, and after them the Romans, carried their conquests into Asia and Africa, where were the dwellings and dominions of Shem and Canaan.

JAPYDES, or IAPODES, a people who stretched along the coast of the Adriatic, from the Gulf of Quarnero, as far as *Zara*, the ancient Jadera, for a distance of 1000 stadia. They occupied the valleys of Mons Albius, which form the extreme point of the Alps to the east, extending in the interior to the Pannonii and the Ister or Danube. They were finally subdued by Augustus after they had twice defeated the Romans within twenty years, attacked Aquileia, and plundered Tergestum or Trieste. Their towns were Metulum, Arupenum, Monettium, and Veudum. They were in the habit of tatooing their bodies. (Strab. vii. 315; Appian. *Illyr.* 18, 19.)

JAQUELOT, ISAAC, a learned French Protestant divine, was born on the 16th December 1647, at Vassy in Champagne, of which place his father was minister. The revocation of the edict of Nantes having obliged him to quit France, he took refuge first at Heidelberg, and then at the Hague, where he procured an appointment in the Walloon church. Here he continued till that capital was taken by the king of Prussia, who, having heard him preach, appointed him his French minister in ordinary at Berlin, to which city he removed in 1702. During his residence at Berlin he entered into a warm controversy with M. Bayle on the doctrine advanced by him in his dictionary concerning Manichæism, which dispute continued until death imposed silence on both parties. It was in this controversy that M. Jaquelot openly declared in favour of the Remonstrants. His reputation as a writer rests principally on the following works, viz. 1. Dissertation sur l'Existence de Dieu, Hague, 1697, in 4to; 2. Dissertation sur la Messe, où l'on prouve aux Juifs que Jésus-Christ est le Messie promis, et prédit dans l'Ancien Testament, Hague, 1699, in 8vo; 3. Traité de la Vérité et de l'Inspiration des Livres du Vieux et du Nouveau Testament, Rotterdam, 1715, in 8vo; 4. Select Sermons, Geneva, 1721, in two vols. 12mo.

JAR, an earthen pot or pitcher, with a big belly and two handles. The word comes from the Spanish *jarra* or *jarro*, which signifies the same thing.

JARCHI, SOLOMON, otherwise *Isaaki Solomon*, a famous rabbi, born at Troyes, in Champagne, who flourished in the twelfth century. He was a perfect master of the Talmud and Gemara; and he filled the postils of the Bible with so many Talmudical reveries, as totally extinguished both the literal and the moral sense of it. The greater part of his commentaries are printed in Hebrew, and some have been translated into Latin by the Christians. They are generally esteemed by the Jews, who have bestowed on the author the title of *prince of commentators.*

JARDYN, or JARDIN, KAREL DU, a painter of conversations, landscapes, and such like subjects, was born at Amsterdam in 1640, and became a disciple of Nicholas Berchem. This painter, in colouring and touch, resembled his master Berchem; but he added to that manner a force which distinguishes the great masters of Italy; and it is observed, that most of his pictures seem to express the warmth of the sun, and the light of mid day. However, some of his subjects are often more extensive, containing a greater number of objects, and a larger design. His works are as much sought after as they are difficult to be met with. He died at the age of thirty-eight.

JARENSK, a town of the Russian province of Wologda, the capital of a circle of its own name, extending over 23,936 square miles, but containing no more than 31,500 inhabitants. It is generally a neglected district, covered with woods, marshes, and lakes. The town is situated on the river Wytscheda, which is usually closed by frost from the beginning of November to the middle of April. It contains 200 houses, and from 1000 to 1100 inhabitants. Long. 47. 33. E. Lat. 61. 20. N.

JARGEAU, a town of the arrondissement of Orleans, in the department of the Loiret, in France. It stands on the left bank of the river Loire, over which is a fine bridge. It contains 428 houses, and 2690 inhabitants. Long. 2. 1. E. Lat. 47. 50. N.

JARMERITZ, a town of the circle of Znaym, in the Austrian province of Moravia, and situated on the river Rokitna. It has near it a magnificent palace and park belonging to the family of Questenburg, with a very extensive library. The town contains 272 houses, with 1650 inhabitants.

JARNAC, a town of the arrondissement of Cognac, in the department of the Charente, in France, on the right bank of the river. It contains 1560 inhabitants, amongst whom are merchants dealing very extensively in brandy for foreign countries. It is celebrated for the great battle fought there in 1569, between the Huguenots and the Catholics, in which the Prince of Condé was taken prisoner.

JAROSLAW, a government of European Russia, formerly in the province of Moscow, to the eastward of Twer, extending over 15,202 square miles. It comprehends twelve cities or towns, 554 parishes, 7705 villages, and 1,022,900 inhabitants. It is an elevated level district. The soil is generally marshy, but mixed with portions of sandy or clayey land. It is miserably cultivated, and though all the population are chiefly occupied in agriculture, it scarcely produces sufficient corn (chiefly rye and barley) for their subsistence. Both hemp and flax succeed tolerably well; and the conversion of these into the various kinds of linen is a means of affording to the inhabitants of the towns occupation and subsistence. The hides of their cattle also form a branch of employment to the people, as does the fishery on the rivers and lakes. The river Wolga enters the province from Twer, and receives the waters of numerous streams that flow through it. There is a lake of eight miles in length and three in breadth, called Rostow, out of which the Kotorosla runs to the Wolga; and thirty-six smaller lakes, all, like the streams, abounding in fish. The Wolga is navigable in its whole progress through the province, as are also the Mologa and the Scheksna, which run into it. The province is divided into ten circles. The capital, Jaroslaw, is also that of the circle of the same name. It stands at the junction of the Kotorosla with the Wolga. It has no other fortification than palisades, but is defended by a fortress. It contains forty-four churches, several convents and hospitals, 2754 houses, and 24,200 inhabitants, whose chief subsistence arises from the linen trade, and Russia leather. Long. 30. 4. 55. E. Lat. 57. 57. 30. N.

JAROSLAW, a city in the circle of Przemysl, in the Austrian kingdom of Gallicia, and situated on the river San. It contains a minster and six other churches, for Catholics, Greeks, and Protestants, with 1400 houses, and 6975 inhabitants, occupied in linen and woollen manufactures, and in distilleries. It was a part of the ancient kingdom of Poland, and is still the property of Prince Adam Czartoryski, a nobleman of the country. Long. 22. 47. E. Lat. 49. 59. N.

JASHER, THE BOOK OF. This book is mentioned by Joshua, and referred to in the following passage: "And the sun stood still, and the moon stayed, until the people had avenged themselves upon their enemies: is not this written in the book of Jasher?" It is difficult to determine what this *book of Jasher*, or "the upright," is. St Jerome and the Jews believed it to be Genesis, or some other book of the Pentateuch, in which God had foretold that he would do wonderful things in favour of his people. Huetius supposes it to have been a book of morality, in which it was said that God would subvert the course of nature in favour of those who put their trust in him. Others pretend that it was public annals, or records, which were styled *just*, or *upright*, because they contained a faithful account of the history of the Israelites. Grotius believes that this book was nothing else than a song, composed to celebrate the miracle, and victory therewith connected. This seems the more probable opinion, because the words cited by Joshua as taken from the work, "Sun, stand thou still upon Gibeon, and thou moon in the valley of Ajalon," are such poetical expressions as do not accord with historical memoirs; besides that, in the second book of Samuel (i. 18), mention is made of a book under the same title, on account of a song composed on the death of Saul and Jonathan.

JASLO, a circle of the Austrian kingdom of Gallicia, extending over 1354 square miles. It contains five cities, eleven market-towns, and 366 villages, inhabited by 195,200 individuals, occupying 28,562 houses. It consists of part of the Carpathian Mountains, and the soil is for the most part poor and stony; but it produces corn equal, with the aid of potatoes, to the consumption. The capital is the city of the same name, situated at the junction of the rivers Jastel and Wisloka, and containing 224 houses, and 1463 inhabitants.

JASON, chief of the Argonautic expedition, was son of Æson, king of Iolcos, and of Alcimede or Polymede. His father was obliged to yield to the superior power of his brother Pelias, and was driven from his kingdom. Jason was secretly carried by his mother to the valleys of Mount Pelion, and there delivered into the hands of Chiron the centaur. By him he was trained to the arts of war, and began his adventurous career by joining in pursuit of the Calydonian boar. Then, in obedience to the orders of an oracle in Magnesia, he presented himself at Iolcos to reclaim the kingdom, covered with the skin of a leopard, and armed with two javelins. Pelias had been warned by an oracle to beware of a man who should appear with one foot shod and the other uncovered. Jason, by some accident, entered Iolcos in this manner, and the suspicions of Pelias were of course immediately excited. He boldly demanded the kingdom, to which he was the rightful heir; but Pelias prevailed on him to proceed to Colchis to get possession of the golden fleece, promising on his return to resign the crown. He was accompanied in this expedition by all the bravest of the Greeks (see Argonauts); and, after many curious adventures, they all arrived in safety in Colchis. Jason proceeded to present himself at the court of Æetes, and explained to him the object of his voyage. The king agreed to restore the golden fleece, provided he submitted to certain conditions the former would impose on him. He must tame brazen-footed bulls, whose nostrils breathed flames, and plough with them a field sacred to Mars. He must then kill a dragon which kept watch day and night over the golden fleece, and sow in the field which he had tilled the teeth of this serpent, from which armed men would spring, ready to attack him. The destruction of Jason seemed inevitable, but he was extricated from his difficulties by Medea, the king's daughter. His lofty bearing, and the intrepid nature of the enterprise, had captivated the heart of Medea, and she determined to deliver her lover from all his dangers, if he promised her eternal fidelity. By her magic herbs, he performed the conditions, to the astonishment of Æetes and his subjects; and, having obtained possession of the golden fleece, returned to his native country, accompanied by Medea, whom he afterwards married. Medea, however, carried along with her Absyrtus, her brother; and when she heard that her father was in pursuit, she tore him to pieces, and scattered his limbs in different places, that she might escape whilst her father was employed in collecting the mangled body of his son. They arrived in safety in Iolcos, where they were received with the greatest joy. Æson was restored to youth again by the magic power of Medea; and Pelias, the usurper of the crown, wishing to be restored to the flower of youth, allowed himself to be cut up by his daughter at the persuasion of Medea, and thrown into a boiling caldron. Thus Pelias perished by a miserable death. But Jason was obliged to fly with Medea, and proceed to Corinth, where they lived in great harmony for four years. At the end of that time, having divorced Medea, he married Glauce, or Creusa, daughter of Creon, son of Sisyphus, king of Corinth; but his inconstancy was severely avenged. Medea slew his sons in his presence, and burnt Creusa, together with Creon and Jason. Another tradition states that they returned to Colchis, and reinstated on his throne Æetes, whom a faction had expelled.

JASPER, a species of mineral belonging to the siliceous genus of stones, and of which there are many varieties, some of them extremely beautiful, which are much sought after, and employed as trinkets and ornaments. See Mineralogy.

JASPONYX, an obsolete term in mineralogy, importing, as appears from the name, a compound of jasper and onyx.

JASSY, a city, the capital of Moldavia, the residence of the prince, of a Greek archbishop, and of many of the waywodes or nobles. It stands on a lofty situation, but is surrounded with hills still higher. It is watered by brooks forming a stream ending in the Pruth. The town is composed chiefly of wooden houses, and is said to be excessively filthy, and by no means healthy. The palace of the prince is plain, small, and badly situated. The city contains no less than forty-three churches, with twenty-six convents and nunneries of the Greek religion. It has also a Catholic and a Lutheran chapel. The houses are stated to be six thousand in number, and the inhabitants from twenty-five to thirty thousand. It is not a place of any other trade than such as arises from providing for the luxuries of a voluptuous nobility and a petty sovereign. Long. 27. 24. 55. E. Lat. 47. 8. 30. N.

JASTROW, a city of the circle of Deutschkrone, in the province of East Prussia, situated on a brook running to the river Kuddow. It contains 296 houses, and 2380 inhabitants, of whom more than 400 are Jews. There is a manufactory for arms and military clothing.

JAUER, a city, the capital of a district of the same name, in the circle of Herschberg, of the Prussian province of Silesia. It stands on the river Neisse, is surrounded with walls and ditches, and contains one Lutheran and five Catholic churches, 604 houses, and 5230 inhabitants, chiefly occupied in the several branches of the linen manufacture.

JAULNAY, a town of the arrondissement of Poitiers, in the department of the Vienne, in France, on the river Elain, with 245 houses and 1476 inhabitants. Close to this town was fought, in 1356, the battle usually called that of Poitiers, and sometimes Maupertuis, in which Edward the Black Prince defeated the French army, and made King John a prisoner.

JAUNDICE (derived from the French *jaunisse*, yellowness, of *jaune*, yellow), a disease consisting in a suffusion of the bile, and a rejection thereof to the surface of the body, whereby the whole exterior habit is discoloured.

JAUTS, a people of Hindustan, who have at different times made some figure in its annals. The first historical mention of them occurs at the beginning of the eleventh century, on the invasion of India by Mahmoud the Gaznevide. That conqueror found them established on the eastern bank of the Indus, prepared to oppose his passage. For this purpose they had mustered a large fleet of boats, to the number, according to some accounts, of eight thousand. They were completely defeated, however, and driven into the mountainous districts in the interior of India.

From this time the Jauts remained in obscurity, till the reign of Aurungzebe. Churamana, a Jaut of some distinction, collected then some troops of banditti, with whom he began to commit depredations on travellers. Popular and enterprising, he gradually rose from a captain of robbers to be a powerful chieftain; and, availing himself of Aurungzebe's absence in the Deccan, became the terror of the country round. He had even the audacity, on one occasion, to plunder the rear of that monarch's army; and, when pursued, took refuge among the mountains of Narwar, where he eluded all attempts to extirpate his force. Under the growing imbecility of Aurungzebe's successors, the Jauts continually extended their power, till at length, during the weak reign of Mahommed Shah, and under their enterprising head, Sooraje Mull, it rose to its utmost height. That chief wrested continually new concessions from the weak emperor, till he was able almost to dictate the counsels of the Mogul court. A reverse, however, took place on the invasion of Northern India by Ahmed Shah, the sovereign of Caubul. Sooraje Mull, having opposed that invader, saw his territory overrun, and was obliged to seek aid from the Mahratta power. When the Mahrattas, however, invaded Delhi, the Jaut chief went over to Ahmed Shah, and offered to atone for former hostility by his services on that critical occasion. The battle of Panniput followed, in which the Mahrattas were totally routed, and their power for the time entirely broken. Ahmed Shah rewarded the services rendered by his new ally in this hour of need, by the important cession of Agra and its district. Sooraje Mull, and his son Jowalier Sing, made repeated attempts to obtain possession of Delhi, but were always baffled by untoward circumstances. Jowalier Sing was assassinated by an impostor, who had undertaken to initiate him in the secret of the philosopher's stone. He left his son an infant; a circumstance which, affording an open field to the dissensions of the chiefs, weakened the Jaut power, and rendered it unable to contend with the other fierce competitors for the spoils of the Mogul. In their contests, particularly with Nujeeph Khan, they were gradually stripped of all their possessions, and at length reduced to the fortress of Bhurtpore, with a small surrounding district. When the British power became predominant in this part of India, Runjeet Sing, rajah of the Jauts, sought security by concluding a treaty with Lord Lake, by which, on engaging to assist Britain against all enemies, he not only retained the internal government of his territories, but was even exempted from paying any tribute. Yet, in 1805, after the defeat of Holkar, he received that chief, with his discomfited army, into Bhurtpore. The place sustained a most desperate siege, and cost the British army an immense number of lives. At length the rajah, despairing of effectual resistance, agreed to compel Holkar to quit the place, and to give it up to the British, on condition of retaining the government of his territories, and the fortress of Deeg. He was obliged, however, to pay twenty lacs of rupees, and to give ample security for a more faithful observance of this treaty than of the former.

JAVA.

This large and fertile island belongs to the group which modern geographers denominate the Sunda Islands. It extends eastward, with a slight deviation on the south, from 105. 11. to 114. 33. of east longitude from Greenwich, and lies between the latitudes of 5. 52. and 8. 46. south. It is in length, between Java Head and the south-east point of the island, 666 statute miles; and its breadth varies from 135½ miles, between the south-west point of Pachitan Bay and the north point of Japara, to fifty-six miles, between the mouth of the Serayu River and the Marabaya. Its area is estimated at 50,000 miles. On the south and west it is washed by the Indian Ocean; to the north-west by a strait called the Straits of Sunda, which separates it from the island of Sumatra at a distance, at the narrowest point, of only fourteen miles; and on the south-east by the Straits of Bali, only two miles wide, which divide it from the island of that name. These islands, and others stretching eastward, form with Java a gentle curve of more than 2000 geographical miles. From the eastern peninsula of India, Java is distant 140 leagues, from Borneo about fifty-six leagues, and from New Holland 200.

Aspect of the country.

The island of Java is of a rectangular form, so that if it were divided into five or six parts, each would form a parallelogram. It is extremely diversified on its surface. An uninterrupted range of lofty mountains, varying in elevation from 5000 to 11,000 and even 12,000 feet above the level of the sea, and exhibiting in their round bases or pointed tops their volcanic origin, extends almost east and west through the whole length of the island. They rise to their greatest elevations towards the centre, which is much broken. The tops of these mountains were formerly the craters of volcanoes, which are now extinguished, though many of them emit smoke after heavy rains. From this great chain other innumerable ranges of hills of inferior height run in various directions, and serve to form and confine plains and valleys of different elevations and extent. These mountainous regions present all the most romantic and highly diversified scenery which is to be found amid waving forests, never-failing streams, and constant verdure, heightened by a pure atmosphere, and the glowing tints of a tropical sun. The aspect of the northern coast is low, in many places swampy, and overgrown with mangrove trees and bushes, particularly towards the west. But in advancing five miles inland a sensible improvement is experienced in the atmosphere and climate. Every step in advance leads to a purer air and a brighter scene. Here, amid the mountains, are found elevated and fertile plains, the seat of industry and skilful cultivation. "Here," says Sir Stamford Raffles, "stupendous mountains are clothed with abundant harvests, impetuous cataracts tamed to the peasant's will. Here is perpetual verdure; here are tints of the brightest hue. In the hottest season the air retains its freshness, in the driest the innumerable rills and rivulets preserve much of their water. This the mountain farmer directs in endless conduits and canals, to irrigate the land, which he has laid out in terraces for its reception; it then descends to the plains, and spreads fertility wherever it flows, till at last, by numerous outlets, it discharges itself into the sea."[1] The principal harbour is that of Sourabaya, in the eastern districts, formed by the approaching extremities of Java and Madura, which is broad and spacious, and secure against the violence of the sea and the wind. The next in importance is that of Batavia, more properly the roads of Batavia, which

[1] See *History of Java*, by Sir Stamford Raffles, vol. i. p. 24.

Java.

are sheltered by several islands lying in the outer part of the bay. There are other positions along the northern coast which might be improved into convenient harbours, though the whole coast affords excellent anchorage at moderate depths during nearly all seasons of the year. In the smooth sea and moderate weather which usually prevail, the native vessels and small craft always find sufficient shelter at the change of the monsoon, when it is dangerous to anchor on the coast, by running for shelter under some of the islands which are scattered in those seas, or passing up the rivers, which, though presenting a difficult entrance, from the mud banks, that form a bar at their mouth, are mostly navigable for small vessels as far up as the maritime capitals through which they run. The south coast, which rises into high and rugged cliffs, is inaccessible, with the exception of a few bays, on account of its exposure to the open sea, and the violent surf which in consequence dashes against it.

From the mountains of Java numerous streams pour down into the plains. There is no space, indeed, for the formation of large rivers. But there are probably no less than fifty which in the wet season bear down rafts of timber and other rough produce of the country, and not less than five or six at all times navigable to the distance of some miles from the coast; and those which are useful to the agriculturist for the irrigation of the lands cannot be numbered. The principal rivers are the Solo, the largest in the island, which discharges itself on the north side by two principal outlets into the sea near Gressek, and by which the produce of an extensive country is carried down in flat-bottomed boats to the sea. The river of Sourabaya, which is the second in magnitude, falls into the sea by five outlets near Sourabaya. There are several smaller rivers in these eastern districts, which fall into the ocean on the northern shore, and which are highly useful for the conveyance of teak timber from the interior forests to the coast; or which, being directed into canals, tend to improve the inland navigation of the country. Towards the west, the principal rivers which fall into the sea on the northern coast are the Chikandi, the Chidani, the Chitaram, and the Chimanok. Those which discharge themselves by the south coast are the Chimandiri, which falls into the sea at Wyn-Coop's Bay, the Chitandui, the Serayu, and others. Along the northern coast almost every district has its principal river, but they have all the disadvantage of being blocked up at their entrance by the accumulation of mud banks, an evil which is increasing with the extension of agriculture, from the quantity of soil necessarily washed down in the process of irrigating the land for the cultivation of rice. Java contains no lakes of any considerable size, though there are several very beautiful lakes of small dimensions among the hills, many of which are the craters of extinguished volcanoes. There are also extensive swamps, which, though they are filled with water during the wet season, are for the rest of the year dried up or choked by vegetation.

Soil and climate.

Java possesses a soil that is extremely rich, and remarkable for its depth, owing, as Sir Stamford Raffles conjectures, to the exclusively volcanic constitution of the country, and the quantity of new mould that is constantly washed down the sides of its mountains. The best soil resembles the richest garden mould in Europe. The seasons, as in all tropical countries, are distinguished into wet and dry, and depend on the periodical winds, or the monsoons. The west monsoon, which brings on the annual rains, begins in October, and becomes more steady in November and December; it continues till the latter end of February or the beginning of March. It often blows with great violence, and is accompanied with heavy rains, which renders this the most unhealthy season. The month of April ushers in the easterly winds and fair weather, which continue for the remaining half year. But the rains, though they often fall in torrents, are not so constant nor so violent as on the continent of India. During the rainy season there are days free from showers; while, again, in July and August, occasional rains refresh the atmosphere, and preserve the brightest verdure of the landscape throughout the year. Thunder-storms are frequent, and the lightning very vivid. The thermometer on the northern coast, at Batavia, Semarang, and Sourabaya, occasionally rises, about three in the afternoon, to 90°, which it rarely exceeds; but in general it has been found to range between 70° and 74° in the evenings, and 83° at noon, or at Semarang 87°. At thirty or forty miles inland from Batavia, on the mountains, it ranges between 60° and 70°, above which it seldom rises. On the hills of Semarang, where Europeans frequently reside during the dry season, at an elevation of about 4000 feet, it is frequently, in the mornings, as low as 45°, and ranges between 50° and 62°; and on the summit of one of the highest mountains, Sindoro, it has been seen as low as 27°.[1] From its insular situation, Java enjoys the benefit of the land and sea breeze; and its diversified surface affords the choice of climate, and a regular diminution of temperature, in proportion to the elevation. With the exception of the city of Batavia, where the climate is the most baneful in the world, and the low marshy flats on the northern shore, the island of Java is, in point of salubrity, equal to the healthiest parts of British India, or of any tropical country in the world. This fact is attested by the medical registers of the different British regiments stationed in this island. From the 1st November 1813 to the 1st November 1814, the deaths among 7470 British troops, who were exposed to many disadvantages and privations, did not exceed 504, which was only in the proportion of 1 to 14. From November 1814 to November 1815, out of 7487 troops, 252 died, 63 by fever, 123 by dysentery, and 65 by other diseases, which is only in the proportion of 1 in 30 in a year; a low estimate for climates that have borne a better character for salubrity than that of Java.

Vegetable produce.

This island abounds in the number and extraordinary variety of its vegetable productions. Between the tops of the mountains and the sea-shore is comprised almost every degree of temperature, and hence the produce of every region finds here some congenial spot. Rice, of which there are a hundred varieties, is cultivated on all the low grounds and ravines along the sea-coast, and in other situations commanding a supply of water. It is the great staple of agriculture in Java, to which every other species of husbandry is subordinate; and this island is the granary of the eastern archipelago, from which all the other adjacent islands and states of Sumatra, Molucca, Borneo, Celebes, and the Moluccas, have been long supplied; while every year about six or eight thousand tons were formerly sent by the Dutch to Ceylon, Coromandel, the Cape, and their other settlements. Notwithstanding this abundant produce, it is calculated that about seven eighths of the island are either neglected or badly cultivated; and such is the fertility of the soil, that it is from the remaining one eighth that these great supplies are derived. Maize or Indian corn ranks next in importance to rice, and is principally cultivated in the higher regions, and in those tracts where there are no mountain streams for the irrigation of the soil. Its cultivation has of late been extended in Java, and is becoming more and more a favourite article of food. Wheat has been introduced by the Europeans, and cul-

[1] See Raffles' *History of Java*, vol. i. p. 36; *Batavian Transactions*, vol. viii. Introductory Discourse.

tivated with success to an extent required by the European inhabitants. It thrives well in the interior of the country. Oats and other grain thrive in those parts of the island, and would be produced in great abundance were due attention given to their culture. Potatoes have been cultivated during the last forty years, in elevated situations, near all the principal European establishments, and are found of a good quality; also most of the common culinary vegetables of Europe, though their quality is apt to degenerate unless fresh supplies of seed be procured from Europe. Other species of grain, and leguminous vegetables, and a variety of pulses, are raised as green crops in intervals between those of rice; and in times of scarcity the natives make use of various kinds of the plantain, also the yam and the sweet potato. But in general Indian corn is the only article used by some as a substitute for rice. Cotton of an inferior quality to the Indian cotton is cultivated in almost every part of the island, and its cheapness occasions a considerable exportation. The coffee plant thrives luxuriantly in Java. It was first introduced about the year 1723 by the Dutch, who established a monopoly of the article, and forced the natives to cultivate it, and deliver it into the government stores at a reduced price. During the French administration of Marshal Daendels this cruel oppression was carried still further, and in certain districts every family was forced to take care of a thousand plants, and deliver the produce into the government stores. Under the more humane rule of the British governor, Sir Stamford Raffles, the free cultivation of coffee was permitted to the inhabitants, and all compulsory labour was abolished. The quality of the Java coffee is reckoned superior to that of the West Indies, and ranks with that of Bourbon in the European markets; its cultivation, for which many parts of the island are eminently adapted, has therefore been greatly extended; and it is exported to the amount of twenty-six millions of pounds, which is about two sevenths of the produce of the West Indies. The soil is very favourable to the growth of tobacco, which was introduced by Europeans, and is now extensively raised for exportation in the central districts of the island, about five millions of pounds being sent to the rest of the archipelago. In some parts it forms, after rice, the most important article of cultivation. Pepper was at one time the principal export from Java; but it was strictly monopolized by the government, and the most oppressive modes were resorted to in order to enhance its price. For some time past it has ceased to be cultivated to any extent. Indigo is raised in most parts of the island; and both the climate and soil of Java offer peculiar advantages for the extensive cultivation of this plant. The natives prepare the indigo very unskilfully, and hence it is of very indifferent quality. But if it were more carefully manufactured, it might form a most valuable and important export for the European market.

Notwithstanding the extent to which cultivation has been carried in many districts of the island, large portions of the surface are covered with primeval forests, affording excellent timber for almost every purpose. Extensive forests of teak are found in almost all the eastern provinces, but especially in the central districts of the island. There are great varieties of other kinds of timber, as the *suren* (the *tuna* of Bengal), of which the wood is light, strong, and durable, having something of the smell of cedar, and which, as the grain is not fine, is used for making chests, trunks, and carriages. The *wungu* is often used instead of teak. It is of a somewhat finer grain, and, when in full blossom, is the most beautiful tree existing. The *wadang* or *bayur*, a light wood, is well adapted for the masts and spars of small vessels. There are several other similar woods, of which are formed the handles of spears and pikes. There is a close and ponderous wood, the *nangka*, which is used for beams and rafters in the construction of houses, and sometimes for household furniture. There are other woods, heavy, hard, and close in the grain, which are used for the anchors of small vessels, for ships' blocks, for naves of wheels, for handles of tools for carpenters and other artificers, for cart-wheels, for machinery, and such like purposes. There are other light woods, which are useful for canoes, for the handles of axes and other like tools, and which are manufactured into planks. There are various descriptions of woods that are well adapted for household furniture, cabinet ware, &c. of a deep-brown or black colour, and which take a fine polish; others of a lighter colour, and finely grained, that are used for inlaying. There are other kinds of woods of various colours, variegated, white, and black, or of yellowish or brown colours, and very heavy, which are employed for canes, handles, and spears. The bamboo flourishes in great luxuriance and variety. The rattans of Java are, however, inferior to those of Sumatra and Borneo. Many woods afford excellent fuel; and amongst the useful trees may be reckoned the soap tree, of which the fruit is very commonly used in the washing of linen; the *kasemak*, from the bark of which is made a varnish for umbrellas; the *oampang*, from the resin of which the natives prepare a shining varnish for the wooden sheaths of krises; the cotton-tree, from which a silky wool is obtained for stuffing pillows and beds; the wax-tree, from the kernel of which an oil is expressed, which some time after becomes hard, and bears a resemblance to wax, and may be burnt in lamps or converted into candles, affording when burning an agreeable odour; the shrub is also produced which yields the elastic gum from which the India rubber is prepared. This substance is converted into torches, which are employed in searching for edible bird-nests in the caves of the rocks. Few of the trees in Java exude the odoriferous resins which abound in Sumatra, Borneo, and the eastern islands. The camphor tree is unknown. None of the finer kinds of spices, such as the nutmeg, the clove, or the cinnamon, are indigenous to Java; but the few trees planted by Europeans in gardens have thriven well, and there is little doubt that the nutmeg and the clove might be extensively cultivated throughout the island. The vine would also thrive well in some of the eastern provinces; but its growth was always discouraged by the narrow policy of the Dutch, who were afraid lest it should interfere with the wine trade of the Cape of Good Hope. The cottage of every peasant is surrounded with plantations of cocoa-nut trees, which constitute an inheritance that is transmitted from father to son, and which it is reckoned a sacred duty to transmit, and to augment by new plantations. The various species of the palm-tree are found in Java; and, besides the cocoa-nut, there are many trees growing spontaneously, of which the seeds and kernels are used as food. The true sago of Amboyna and the eastern islands is found in a fair, low, and marshy situation, though the preparation of it from the pith of the tree is not known to the inhabitants of Java; but from the *aren* or *sagurus rumpnii*, which abounds in all parts, and, from its various and extensive uses, ranks next in importance to the cocoa-nut, a substance is prepared similar in all respects to the true sago of the eastern islands. Other trees exude gums and balsamic oils. The kubab yields a balsamic oil or jelly, which is much esteemed, which has the smell and taste of camphor, and is taken inwardly for violent coughs, or disorders in the stomach. The benzoin-tree produces an odoriferous gum, of an orange colour, which is a valuable article of commerce. The *upas* or famous poison-tree of Java has long attracted the curiosity of naturalists, and has been the subject of many wonderful, and, as now appears, fabulous tales. It is one of the largest trees in the forests of Java, and rises with a completely naked stem to the perpendicular height of

Java.

sixty, seventy, and eighty feet, when it sends off a few stout branches. The bark, which in old trees is almost half an inch thick, on being cut yields a milky juice, from which a poison is prepared equal in fatality to the strongest animal poisons hitherto known. The inner bark resembles a coarse piece of linen which is worked into ropes, and which, after much bruising, washing, and immersion in water, is worn by the lower classes when working in the fields. But it is remarkable, that after being exposed to a shower of rain, this dress produces an intolerable itching, the effect of a small portion of the poison still adhering to the bark. The story of the tree poisoning the surrounding atmosphere is altogether a fable. It is extremely difficult to penetrate into the forests of Java, from the quantity of underwood and creeping plants with which they are entangled.

Fruits.

"No region of the earth," says Marsden, "can boast of a greater abundance and variety of indigenous fruits than Java. The *mangustin*, pre-eminent for delicacy of flavour amongst all the fruits of the East, of a round form and a purple colour, is found in great abundance. The *dorian*, a large fruit, like the bread fruit in appearance, of a disgusting smell, and of a flavour like a custard, is said, when seasoned with garlic, to become by frequent use extremely fascinating. The *rambutan*, a cool and agreeable fruit, of a delicate sub-acid flavour, grows on a showy and elegant tree. The *lanseh* or *lanseb*, much relished by the lower classes, grows in clusters like grapes, and has a pulpy substance, with a delicate sub-acid flavour. The *pumplemoos*, the Batavian lembu or vine of Bengal, and the shaddock of the West Indies, is in Java of an exquisite flavour; as also the pine-apple, which is much superior to that of Hindustan. There are besides extensive varieties of the atrocarpus or jack-fruit, which grows wild in abundance; of the mango, of which no less than forty varieties are enumerated; the plantain, the guava, the rose-apple, the custard-apple, the papaw, besides dates, pomegranates, tamarinds, figs, annanas, oranges, lemons, citrons, melons, pumpkins. In some of the mountainous tracts are to be found peaches, Chinese pears, and other fruits imported from Japan, the Cape of Good Hope, and China. Of the oil-giving plants there are many. From the *palma christi* is obtained most of the oil that is burned in lamps. There are numerous trees, plants, and shrubs, which supply, from the bark or the leaves, fibres that are converted into ropes, threads, lines used for fishing, thread, and finally cloth, or spun into a kind of stuff resembling silk, gauze, &c. Mats are made from a kind of grass, and from the leaves of various palms; and the paper in common use amongst the Javans is manufactured from the *morus papyrifera*.

The plants and herbs, and the innumerable flowers which bloom in perpetual succession in Java throughout the year, and impregnate the air with their fragrance, present an inexhaustible field for the researches of the botanist. Many of the flowers are used by the natives in adorning their persons, and are remarkable for their fragrance. From the *fula majori*, of which whole fields are cultivated, a water is distilled superior to rose-water; and from the eglantine tree, originally imported from Persia, a rose-water is distilled which is in great repute. The coral trees, of different species, are all elegant and showy; and amongst the trees and shrubs there are some that are rare and curious, such as the *casuarina equisetifolia*, whose pendent branches resemble the hair of the cassowary. The bombax bears a long pod, which contains a silky substance that is used for stuffing cushions. Many varieties of flowers and plants are cultivated in gardens on account of their beauty and fragrance, such as the elastic gum-tree, the *convolvulus jalappa*, the *styrax liquida*, and the mountain cabbage-tree of the West Indies. The pitcher-plant (*nepenthes distillatoria*) is found in the most arid situations, and is provided with a curious contrivance for retaining the rains or the dews which refresh the parched ground. To the stalk which bears the leaves, a small tube, in the form of a pitcher, and covered with a lid, is attached. By means of a hinge or strong fibre passing over the handle, and connected with the leaf, which is contracted when the weather is showery, or when the dews fall, the lid is opened for the reception of the moisture; and when it is filled it closes again, so firmly as to prevent evaporation, and thus water is secured for the sustenance of the plant. Java produces a variety of medicinal plants, many of which are little known in Europe, though several, whose properties have been investigated, are likely to become valuable articles in medicinal practice. It yields also a great variety of culinary vegetables, such as the kurkum, a favourite plant used by the Malays in cooking their fish and flesh, to which it gives the colour and taste of saffron; the pattatas, reckoned a very wholesome root, and eaten either raw or roasted, in which state it has the taste of a chestnut; the foki-foki, which, when boiled in wine with pepper, tastes like an artichoke. All other garden plants, such as endives, cauliflowers, beans, cabbages, pompions, water-melons, yams, potatoes, &c. are produced in great abundance throughout the island.

Animals.

Neither the camel nor the elephant is found in Java, nor have they either the ass or the mule. But they have a male breed of fine horses, strong, fleet, and well made; and a still finer breed is imported from Buna, or the neighbouring island of Sumbawa, which much resembles the Arabian horse in all qualities excepting size. The bull and the cow are common, and the breed has been improved by a species brought from the continent of India. But the animal of most essential use in agriculture is the buffalo, which is a large and fierce animal, heavier than our largest oxen, and well qualified for a beast of burden. Goats of a small size are numerous; sheep are scarce and small. The hog is principally reared by the Chinese. Wild animals abound in the forests. The royal tiger is here as powerful and as large as in Bengal. There is a smaller species of a black kind which is very ferocious, and in size and shape resembles a leopard; there is also the leopard and the tiger-cat. The rhinoceros is amongst the largest quadrupeds found in Java. It is principally met with in the western parts, lying in the deep jungles of the high grass, remote from observation. Deer and antelopes abound in the woods; also hares and rabbits, as well as all the varieties of the wild hog, which are extremely destructive to the plantations. Other smaller quadrupeds, such as the weasel and squirrel, are common. Amongst the feathered tribes are found the cassowary, called emeu by the Indians, a very large and powerful bird; the white eagle, and several varieties of the falcon; also the carrion-crow and the owl, the peacock, two species of parrots, one of which is very beautiful, and sells at a high price. Birds of paradise sometimes visit the island. Pigeons of the most beautiful plumage are found; also pheasants, jingle and pea-fowl, quail, snipes; wild ducks and geese are not so common. The Java sparrow is a very handsome bird. Amongst the most interesting subjects for the study of the naturalist is the small swallow, which forms edible nests, of which large quantities are annually exported to the Chinese market, where they are considered as a very great luxury. The aquatic tribe are numerous. At the mouths of the rivers the cayman or alligator, more resembling the crocodile of Egypt than that of the Ganges, is found lurking for its prey. The water-guana, in length about six or seven feet, infests the rivers and ponds, where it is very destructive. There are various kinds of lizards; amongst others a small one, which is not above eighteen or twenty inches in length. Two spe-

Java.

cies of the turtle are found in the surrounding seas, which abound also in a variety of excellent fish not known in Europe; and in soles and carp, as well as in oysters and shell-fish of every kind. There are thirty-four species of river-fish, many of which are excellent. In the several bays on the shores of the island are numerous sharks, which are often seen swimming around the ships.

The serpent brood are numerous, and of various kinds. It is uncertain whether the boa constrictor be found in Java. There are several which attain to a very large size, from twenty-five to thirty feet in length. One of these, the *ular lalang*, is much dreaded by the natives, and is said to be poisonous. Scorpions and musquitoes abound in marshes; and there are various sorts of dangerous and disgusting vermin, such as ants, spiders, fire-flies, which swarm in the roads, houses, and even bed-chambers of the inhabitants. In the woods is found a venomous spider, the body of which is nearly two inches in diameter, the fore legs and claws nearly four inches in length, and the webs spun by it so strong as frequently to entangle and catch the smaller birds.

Manufactures.

Manufacturing industry can scarcely be said to exist in Java. Weaving is exclusively practised by the women, who make coarse cloths of cotton, and sometimes of silk, for the use of their families. These they dye of various colours; but, with the exception of blue and scarlet, all their dyes are apt to fade. Tanning is carried on in some districts with tolerable success; also saddlery; and there are manufactures in iron, brass, and tin. Salt is manufactured in Java to a great extent, both for the home supply and also for exportation. Under the Dutch government, the manufacture of salt was farmed out to the Chinese as an exclusive privilege; a system liable to much abuse, and which left the price in a great measure at the discretion of the farmer. The farming of salt was abolished under the British regime in 1813. Saltpetre is obtained in many parts of the island, and whilst the French possessed the island, saltpetre works were established under European superintendents; powder-mills, founderies for shells, shot, anvils, &c. and manufactories of swords and small arms. From the resources and industry of this island alone the French were enabled to equip an army of 15,000 men, besides a numerous militia in every district; a proof of the progress of manufacturing industry amongst the natives. The trade of a blacksmith is held in high estimation, and considered almost as a liberal profession; chiefly, it is probable, on account of the value attached to the manufacture of arms. Their small boats and barks are made of various and convenient shapes; but they fail whenever they attempt to construct vessels of any magnitude.

Commerce.

The commerce of Java was very extensive at the period of the Dutch establishment in the Eastern Seas. "But," says Sir Stamford Raffles, "it would be painful to point out how far, or to show in what manner, that commerce was interfered with, checked, changed in its character, and reduced in its importance, by the influence of a withering monopoly, the rapacity of avarice armed with power, and the short-sighted tyranny of a mercantile administration." The Javans were, prior to this time, plentifully supplied both with gold and jewels, and with other valuable articles, in exchange for the produce of their tranquil industry and their fertile soil. Constant requisitions were made by the government for the services of native vessels, at rates far below a just compensation; and native traders were forbidden to trade in any of the articles of the Dutch monopoly. This traffic was almost entirely annihilated, or diverted from its course, by the restrictive policy of the Dutch, and by their monopolies. The commerce of the country revived under the more liberal administration of the British governor Sir Stamford Raffles, one of those great and enlightened men who seemed to value the possession of power only as it enabled him to benefit mankind. This extension of trade appears from the increasing amount of tonnage employed to carry it on. The shipping that cleared out from the port of Batavia in 1812, was 52,375 tons; in 1813, 64,306; in 1814, 72,718. By an official return in March 1816, it appears that the total quantity of tonnage in vessels boarded in their passage through the Straits of Sunda, amounted, in 1812, to 45,000 tons; in 1813, to 56,000 tons; in 1814, to 64,000 tons; and in 1815, to 130,000 tons; and, adding vessels not boarded, the whole tonnage for four years would amount to 390,000. Java has great advantages for its internal trade, from its navigable rivers, by which the produce of the interior is conveyed to the coast, and from its excellent roads. A high post-road, passable for carriages at all seasons of the year, runs nearly the whole length of the island east and west, a distance of 800 English miles; and a high military one, equally well made, crosses the island from north to south; cross roads branching off from these main roads, so that there is easy access to all parts of the island. The internal trade of the island was, however, heavily oppressed by local duties, rendered still more oppressive in the hands of the Chinese, to whom they were farmed out; and by market duties. From this oppression it was only partially relieved by the British. The coasting and foreign trade of Java is carried on in vessels belonging chiefly to Chinese, Arabs, Bugis, natives of Celebes, and in smaller Malayan craft. The island is a great entrepôt for the produce of the whole eastern archipelago; and its merchants, a great proportion of them Chinese, are very rich, and remarkable for honourable dealing and persevering industry. Java exports for the use of the other islands, including the Malayan ports on the peninsula, rice, a variety of vetches, salt, oil, tobacco, timber, Java cloths, brass-wire, edible bird-nests to the value of L.40,000 or L.50,000, a variety of minor articles, the produce of her agriculture and manufactures, besides a considerable quantity of European, Indian, and Chinese goods. The following articles, the exclusive produce of the eastern islands, are collected at its principal ports for re-exportation to India, China, and Europe; tin from Banca; gold-dust, diamonds, camphor, benjamin, and other drugs, edible bird-nests, biche de mer, rattans, bees' wax, tortoise-shell, and dyeing woods, from Borneo and Sumatra; sandal and other fine woods, nutmegs, cloves, and mace, coarse, wild, and damaged spices, kayu-puti, and other pungent oils, from the Moluccas; horses and sapan wood from Sumbawa; Bugis cloths, and many collections for the Chinese market, from Celebes. A very extensive trade is carried on with China in Chinese junks, about eight or ten of which annually arrive from Canton or Amoi with cargoes of teas, raw silk, silk piece goods, varnished umbrellas, iron pots, coarse China ware, sweetmeats, nankeen paper, and numerous other minor articles, for the use of the Chinese settlers, many of whom come annually to Java, where they employ themselves as labourers on their first arrival; but, by frugal habits and persevering industry, they soon acquire property, and become extensive merchants. European vessels carry out from Java to China, tin, pepper, spices, rattans, and betel-nut; and bring back Chinese produce for the European market, a balance of cash, and manufactures for Batavia. Whilst Java was in possession of the English, all kinds of piece goods, opium, and other articles, were imported from Calcutta, Madras, and Bombay, and bills, gold-dust, bees' wax, tin, Japan camphor, sago, and teak-timber, were taken away in return. Under the English rule the trade was free, and great quantities of teak were imported into the markets of Bengal. But since the island was ceded to the Dutch, the old system has been revived, and the teak of

Java has been artificially raised in price two hundred per cent. The latter is of a superior quality to that of Pegu or the Malabar coast; and, notwithstanding that it was monopolized by the Dutch government, it was exported to the Moluccas, to Malacca, and to the Cape of Good Hope, where all the public buildings are constructed of Javan teak. Large quantities of Javan sugar, which is of a superior quality, were exported to Bombay, and also by Arab vessels to the Red Sea, and particularly to Mocha. But Arab traders of capital have since been driven out of the market by the monopolies of the Dutch. Java, since the partial opening of the Indian trade in 1810, has largely imported European manufactures.

It appears from Mr Crawfurd's statement that there does not exist here the same inveterate prejudice against European manufactures as in India and China. Since the opening of the free trade, the fine cottons of Britain have, from their cheapness, in a great measure superseded those of Hindustan. Chintzes are the favourite article, in which the pattern is of much consequence. The taste of the Javanese is for bright colours, red and green in preference to all others, and next to these yellow and brown; whilst black is unsaleable. The pattern should be small, filling the ground without crowding it. White calicoes and cotton cambrics are also purchased by the natives, to be painted by themselves. Although Java lies under the tropics, its mountainous and maritime situation produces a demand for light woollens. These should be cheap Yorkshire cloths, such as cost at Leeds 5s. to 6s. 6d. per yard. Iron, to the extent of 28,000 cwt., and to the value of L.22,500, is annually imported into Java, which is destitute of that important metal. The Swedish is preferred, though British iron has of late been introduced to a considerable extent. Fire-arms and ammunition are the most saleable articles, but their export has hitherto been prohibited by European governments. There has been recently a great extension of demand for our glass and earthen ware. A constant demand, limited only by the means of the purchaser, is also daily increasing for gold lace, and the other European manufactures used as dress, furniture, saddlery, &c.

Manners of the Javanese.

Amongst the two races of people who inhabit the oriental islands, distinguished into the brown coloured race, and the Papuas or oriental negroes, the natives of Java belong to the former. They are under the middle size, the standard for men being five feet two inches, and for women four feet eleven inches. Their complexion is a yellowish brown, generally without any tincture of red. Of this colour they admire the fair specimens, and their standard beauty is a virgin gold; but they consider the European white as a sickly tint. They have a round face, little black eyes, a small nose, and a large mouth, with thick lips. On the head, beard, and other parts of the body, there is a remarkable deficiency of hair. Compared with the Europeans and southern Asiatics, they are considered by Mr Crawfurd as an ill-looking race; but the opinion of Sir Stamford Raffles is, in this respect, more favourable. Their constitution is healthy, and they seem to attain a longevity equal to that of Europeans. Early marriages are as universal as amongst other Asiatics, a man being scarcely ever known single at twenty-five, whilst an unmarried female at eighteen is considered as an old maid. The lot of the female sex differs considerably from what it usually is among Asiatics. They are by no means immured with the same jealousy; British gentlemen have even been admitted to visit the harems of the sultans and chiefs, where they were received by the ladies with all the dignified propriety of persons accustomed to mix in general society. To women the commercial and pecuniary affairs of the family are almost wholly intrusted. Of these privileges and advantages, however, they are said not always to make the very best use. The right of divorce, with which they are indulged equally with the other sex, is carried by them beyond all excusable limits. It is very common for a woman, before the age of thirty, to have divorced three or four husbands; and Mr Crawfurd had one pointed out to him who was living with her twelfth. No difficulty occurs in regard to the disposal of the children, who, in Java, are never viewed in the light of a burden. Besides being easily supported, they are usually few in number, a circumstance ascribed to the hard labour which the mothers undergo, and the consequent frequency of abortion. Besides the management of the household, they weave all the cloths worn in the family, and perform various other offices which in Europe devolve on the other sex. Polygamy is permitted by law, but it is known only amongst the great; and, even with them, the first wife alone is of their own rank, and mistress of the family; the others occupy a place decidedly inferior. The natives of Java were drawn by their Dutch masters in very dark colours; but the English residents, after careful observation, have described them much more favourably. They are generous, warm-hearted, and susceptible of strong attachments. Their affections of kindred are peculiarly forcible; so that, even in civil contests, those fraternal enmities, so conspicuous in other Asiatic states, are scarcely ever observable. The English, who placed confidence in them, found them honest in the intercourse of common life; and they share only in a slight degree those habits of piracy for which the Malay tribes are so notorious. In society they are uncommonly good humoured, courteous, and polite, and are scarcely ever seen in a passion, unless on those occasions when they are hurried to the last extreme of violence. These unhappily too often occur under the impulse of that violent jealousy and revenge which form their ruling passions. The disregard of human life seems to proceed to an excess amongst them scarcely known in any other quarter of the globe. It is stated that, in any part of Java, an assassin may be hired for the moderate sum of fifteen or twenty shillings; but, in general, the injured party conceives it more honourable to decline this cheap mode of redress, and to seek vengeance with his own hand. Some, driven to the extreme of desperation, run furiously into the streets, and kill indiscriminately all whom they meet, till they are themselves overpowered and cut down. This dreadful atrocity, which, by a corruption of the native term, is called "running a muck," is said, however, to prevail, not amongst the native Javanese, but amongst the other Malay tribes resident in the capital.

Religion.

In the ancient religion of the Javanese, which was undoubtedly derived from Hindustan, Siva, with his family, and Buddha, were the chief objects of adoration. Their temples appear, from the late inquiries of our countrymen, to have rivalled in splendour those erected in the native seats of their religion. In the course of the fifteenth century, the whole island of Java was, by Arab traders and settlers, converted to Mahommedanism. This faith, however, which is generally observed with so much strictness, is professed here in a very loose and imperfect manner. It need only be observed, that wine and spirits are not only used without scruple on ordinary occasions, but are even sometimes produced at religious festivals. An extreme indifference prevails as to all its outward observances. In return, superstitious credulity is common to a degree almost unparalleled. A belief in sorcery is universal. If a person write the name of another on a skull, bone, or leg, and suspend it from a tree on haunted ground, where two roads meet, the laws doom to death, himself, his friends, his children, and his children's children. Availing themselves of this credulity, various persons usually start up, in troubled times, as saints, prophets, or as the descendants of one of the ancient kings of Java, and attract a multitude of followers. Christianity has not obtained any footing in Java; and Mr Crawfurd doubts if it ever will, till the conduct of its Indian professors becomes more conformable to its precepts.

The Javanese language is the most copious and improved of any used in the Indian islands. It has Sanscrit for its basis, but with considerable variations. In the beauty of its written characters it is not surpassed by any of the languages of Asia. It is distinguished by its vast copiousness as to particular, and barrenness as to general terms. Thus there are five names for a dog, and seven for a horse, but no general word for an animal. The abstract terms nature, space, and others of that kind, are entirely wanting. All their literature, as is usual among rude nations, is metrical, and may be divided into lyrical compositions or songs; romances founded on Hindu legends; romances founded on modern story; histories of modern transactions; with legal and ethical tracts, chiefly in prose. Of these compositions, the songs, in which feeling and passion are simply expressed, appear to be the most pleasing. The romances consist chiefly of abridged translations of the Mahabarat and Ramayana, from the Hindu original into a now dead Javanese language called the *Kawi*. These versions, being free from the endless prolixity of the originals, may be read with greater pleasure. Java had no history previous to the Mahommedan invasion; and even now, its annals consist merely of metrical legends, which, being written under the eye of the prince whose deeds they relate, cannot be suspected of very strict impartiality. Besides the rudeness of these compositions, there is an absence of that energy, ardour, and sublimity, which have often characterised the poetry of far ruder nations. This seems justly ascribed to the despotic form of the government, which represses all the nobler sentiments natural to independent man, when individual character is permitted to unfold itself.

Government. The government of Java is more absolute than that of any other part of the archipelago, and differs little in this respect from the great monarchies of Asia. There is no rank but what emanates from the sovereign; and no bounds are set to the marks of respect shown by inferiors to the higher classes. No individual, of whatever rank, can stand in the presence of a superior, not even the heir-apparent in that of the sovereign. Whenever a chief appears in public, all his inferiors must throw themselves into the posture called *dodok*, which may be rendered by the English term "squatting," in which they remain till he disappears. Sir Stamford Raffles describes himself as much annoyed at seeing, in one of his progresses, the whole population of the country quitting their work, and remaining fixed in this uneasy posture as long as he remained in sight. They have a language, or at least a modification of the language, which must be used by the inferior in addressing those of higher rank. The revenue of the sovereign, as is usual in Asiatic despotisms, arises from the rent of all the cultivated lands in the country, levied in kind, and in the enormous proportion of one half of the entire produce. This, however, by the allowance of one sixth for reaping, is reduced to about two fifths. It is paid, not into the treasury, but by the king assigning to each of his officers and servants a certain number of cultivators, whose rents he is to receive. The Javan farmer is supposed, on the whole, to be more mildly treated than the Hindoo.

Population. The population of Java, including the small contiguous island of Madura, was found, by a census taken in 1815, to amount to 4,600,000. Of these, three millions are in the provinces immediately subject to European authority; the rest is subject to the native princes. The principal European capitals, Batavia, Samarang, and Surabaya, contain respectively 60,000, 25,000, and 20,000 inhabitants; the chief native capitals, Surakerta and Yug Yukerta, about 105,000 each. The Chinese, amounting to 94,000, form the most active and industrious part of the population; the manufactures of salt, sugar, and arrack, are solely in their hands. Slavery in Java prevails to a much less extent than in the other islands. The slaves do not exceed 30,000; and none of them are native Javans, but obtained by purchase or capture from Celebes or Borneo. The philanthropic measures adopted by Sir Stamford Raffles, with a view to the abolition of the trade, were seconded by the chiefs, and productive, to a considerable extent, of the desired effect. (F.)

JAVELIN, in *Antiquity*, a sort of spear five feet and a half long, the shaft of which was of wood, with a steel point. Every soldier in the Roman armies had seven of these, which were very light and slender.

JAXT, one of the circles into which the kingdom of Wirtemberg is divided. It is 2112 square miles in extent, and comprehends thirty-one cities, thirty-five market-towns, and 1608 small villages and hamlets, with 336,000 inhabitants, who are chiefly Lutherans, but intermixed with some Catholics and Jews. It is subdivided into fourteen bailiwicks. It is a mountainous district, but none of the elevations exceed 2200 feet. It is the source of several rivers, some of which run to the Rhine, and others to the Danube. It is a fruitful province, and better cultivated than most parts of Germany; and it yields abundant crops of wheat, summer and winter barley, rye, oats, potatoes, hemp, flax, and rape-seed. Vineyards are numerous, and produce excellent wine. Its mineral products are iron, vitriol, marble, and alum, and abundance of salt is prepared from natural saline springs. The breed of cattle is good, and forms a part of its exports to France. There are manufactories, chiefly of linen. On the whole, this is the most prosperous circle of the whole kingdom.

JAY, GUI MICHEL LE, distinguished by the Polyglott which bears his name, was born at Paris in 1588. He studied the ancient languages, in which, however, he was but moderately skilled. In 1615, three men of rare merit, Cardinal Duperron, Jacques de Thou, and François de Brèves, had conceived the project of publishing a Polyglott; but, from some circumstances, the design was not carried into effect. Lejay, however, resolved to revive the scheme, and conduct it to a conclusion. He had fortune, he was laborious, and he was not wanting in resources. He associated with himself in the undertaking some of the most learned men of his time. The elder Morin of the Oratory, Philippe d'Aquin, a converted Jew, Godefroy Hermant, a canon of Beauvais, and three Maronites of Lebanon, were charged with revising the different books of the Holy Scriptures, each in the language which he understood; whilst Jacques Sanlecque, a famous artist, cast the characters, and Antoine Vitré or Vitray, printer to the king, undertook the impression. It commenced in 1628, and, after encountering a variety of difficulties and obstacles, was completed in 1645, under the title of *Biblia Hebraica, Samaritana, Chaldaica, Græca, Latina, Arabica, quibus textus originales totius Scripturæ sacræ, quorum pars in editione Complutensi, deinde Antuerpiensi regiis sumptibus extat, nunc integri ex manuscriptis toto fere orbe quæsitis, exemplaribus exhibentur*, in ten volumes. The execution of this work is magnificent; it is indeed a masterpiece of typography; but it literally swarms with blunders, editorial as well as typographical; whilst, by reason of the enormous size of the volumes, the use of them is attended with much inconvenience. Lejay ruined himself by the impression, first, because he would not suffer it to appear under the name of Cardinal Richelieu, who, after the example of Cardinal Ximenes, was ambitious of immortalising his name by such an undertaking; and next, because he made it too dear for the English market, upon which Dr Walton undertook his Polyglott Bible, which, being more commodious, reduced the price of Lejay's. After the death of his wife, Lejay, having taken orders, was made dean of Vezelay, in the Nivernois; and Louis XIV. gave him the post of councillor of state.

JAYES, a town of Hindustan, in the nabob of Oude's territories, fifty-five miles south-east from Lucknow. Long. 81. 30. E. Lat. 26. 15. N.

JAYNAGUR, a town of Hindustan, in the province of Bahar, 122 miles south-south-west from Patna. Long. 84. 25. E. Lat. 24. 1. N.

JEALOUSY is that peculiar passion which arises in the mind from fear that some rival may rob us of the affection of one whom we greatly love, or suspicion that he has already done so. The first sort of jealousy is inseparable from love, before it is in possession of its object; the latter is often unjust, generally mischievous, and always troublesome.

JEAN D'ANGELY, an arrondissement in the department of La Vendeé, in France, extending over 334 square miles, divided into seven cantons, and these into 128 communes, with a population of 70,261 persons. The capital, which gives its name to the arrondissement, is a city situated on the river Boutonne, containing 5460 inhabitants, who are partly employed in the manufacture of serges, druggets, and other kinds of woollen goods, and carry on a considerable trade in wine and brandy. There is also an establishment for making gunpowder. It is in long. 0. 40. 5. W. and lat. 45. 55. N.

JEAN DE LUZ, ST, a town of the arrondissement of Bayonne, in the department of the Lower Pyrenees, in France. It is situated on the sea-shore, on the river Nivelle, and is defended by a fort at the mouth of that stream. It contains about 600 houses, with 2830 inhabitants, and is a place of considerable traffic, being the last town of France on the road to Spain; and it carries on extensive fisheries. Long. 2. 15. 7. W. Lat. 40. 23. 15. N.

JEARS, or GEERS, in nautical language, an assemblage of tackles, by which the lower yards of a ship are hoisted along the mast to their usual station, or lowered from thence, as occasion requires; the former of which operations is called *swaying*, and the latter *striking*.

JEBNA, a town of Palestine, on the site of the ancient city of Gath, containing the remains of a fortress built during the crusades by Foulques, king of Jerusalem; ten miles south of Jaffa.

JEBUSÆI, one of the seven ancient peoples of Canaan, descendants of Jebusi, Canaan's son; so warlike and brave as to have stood their ground, especially in Jebus, afterwards called *Jerusalem*, down to the time of David. (Judges, i. 21; 1 Sam. v. 6.)

JEDBURGH, a royal burgh, the seat of a presbytery, and the capital of a parish of the same name, as well as the county town of Roxburghshire in Scotland. It is beautifully situated in the romantic valley of the Jed, on the left bank of that stream, environed with sylvan banks, and embosomed in venerable orchards. This town is of very ancient date, and the name appears to have been at a former period indiscriminately written Gedworde, Jedworth, Jedwood, Jeddart (still in use amongst the common people), and Jedburgh. The name of the river being anciently written Ged, and perhaps Gad, has afforded an opportunity for antiquaries conjecturing that this parish was the principal seat of the Gadeni, a tribe who inhabited the district between the river Teviot and Northumberland. In the twelfth century David I. founded a monastery here, which greatly enhanced the importance of the town. From the antique choir which remains, in a dilapidated state, some have been led to suppose that a sacred edifice existed on the same site prior to the time of David I., and that the venerable ruin, which still attracts much attention, was not founded, but only rebuilt, by that munificent monarch. He also gave to the canons the chapel of Scarsburgh, lying in a recess of the forest, to the east of the Jed; and at a later period the dependencies of Restennet in Angus, and Cannoby in Dumfriesshire, came into the possession of the monastery. The importance of the town was still further secured by the erection of a castle; but by whom it was founded is not known. It was a royal residence, and for ages continued a place of great strength, the object of eager dispute to the contending kingdoms. It was frequently honoured with the presence of the Scottish monarchs, and was the scene of the royal festivities of Alexander III. on the occasion of his second marriage. After the fifteenth century, the town is frequently mentioned in the history of the wars between the Scotch and English. It was burned by the Earl of Surrey in 1523, at which period it appears to have been a very considerable town; for Surrey, in his despatches to Henry VIII. says, that "there was two times more houses therein than in Berwick, and well builded, with many honest and fair houses in garrison, and six good towers therein." The same writer also extols, in no measured terms, the warlike character and bravery of the men of Jedburgh. Their favourite weapon was the Jedwood axe; and their war-cry or slogan, "Jedworth's here." But an account of the various battles and skirmishes in which they distinguished themselves belongs rather to the history of the county, than to a description of the town. At the present day, Jedburgh has four principal streets, crossing each other at right angles, and terminating in a square or market-place. They are wide and clean, and the houses are well built. In recent times the town has been generally improved, and many elegant, if not spacious buildings have been erected. It contains numerous handsome shops, in which all the necessaries and most of the luxuries of life can be readily obtained. It is celebrated for the production of excellent bread, which is exported in great quantities to the north of England, as well as to the surrounding villages of the county. It is entitled to hold two markets every week, on Tuesday and Saturday. The Tuesday's market is well attended, and grain is then sold by sample to a considerable extent. There are two banks in Jedburgh, branches of the British Linen Company and of the National Bank. Besides the established church, Jedburgh contains several meeting houses for dissenters, who are here a numerous body. The principal manufactures are blankets, flannels, tartans, shawls, shepherds' plaidings, hosiery, lamb's-wool yarn, and carpets; and the town also derives part of its income from fruit, which is produced in considerable quantities in private gardens. There is here an excellent grammar and English school, united in 1804, several subscription libraries, a savings bank for the district, a dispensary, one or two religious societies, and there are letter-press printers in the town. An establishment for making printing presses, on a new principle of construction, has likewise been of considerable benefit to Jedburgh. It is governed by a council, consisting of a provost, four bailies, a dean of guild, and eighteen ordinary councillors. There are eight incorporated trades, who annually elect their own deacons and office-bearers, and four of these deacons are admitted into the council to represent the trades for the year. Jedburgh unites with Haddington, North Berwick, Lauder, and Dunbar, in sending a member to parliament. The revenue of the burgh amounts at present to L.573 per annum, being chiefly derived from the rent of the mills. Jedburgh is forty-six miles south of Edinburgh, ten west of Kelso, and twelve north of the borders of England. The population of the burgh amounted in 1821 to 2500, and in 1831 to 3709.

JEDO, or Jeddo, a large city of Japan, the residence of the emperor, and the capital of the country, as it is by much the largest city of the empire, from the resort of princes and lords, who, with their numerous families and servants, swell the train of the imperial court. It is situated in the province of Musasi, in 35. 32. of north latitude, on a large plain at the end of the gulf, which is so shallow, with a muddy clay at the bottom, that no ships of any considerable size can come up to the city, but must be unladen a league or two below it. According to the Japanese accounts, the city is seven miles long, five broad, and twenty in circumference. It is not enclosed with a wall, but is intersected by many broad ditches and canals, with high ramparts raised on both sides, on the top of which are planted rows of trees. A large river, rising to the west of the city, runs through it, and loses itself in the harbour. It sends off a branch, which divides itself into five channels, over each of which is a stately bridge. Jedo is not so regularly built as most other cities of Japan, though in some parts, which have been burnt down and rebuilt, the streets cross each other at right angles. The houses are small and low, being built of wood, with thin clayed walls, divided within into rooms by paper screens, the floors covered with fine mats, the roofs with shavings of wood. They consist entirely of combustible materials, so that we need not wonder at the havoc which fires frequently occasion. In this city are many stately palaces, the residences of the nobles and princes, who are obliged to reside six months of the year at the imperial court. They are distinguished from other houses by large court-yards and stately gates; fine varnished staircases, of a few steps, lead up to the door of the house, which is divided into several magnificent apartments, all on one floor, only one story high, and not adorned with towers, as the castles and palaces are where the princes and lords of the empire reside in their hereditary dominions. There are, besides, numerous temples, monasteries, and other religious buildings. The castle and residence of the emperor, which is a magnificent structure, is situated about the middle of the city. It is of an irregular figure, inclining to the circular, and is five Japanese miles in circumference. It consists of two enclosures; the innermost and third castle, which is properly the residence of the emperor; two other strong, well-fortified, but smaller castles at the sides; and some large gardens behind the imperial palace. The first and outermost castle takes in a large space of ground, which encompasses the second and half the imperial residence, and is enclosed with walls and ditches, and strong, well-guarded gates. This is the residence of the princes of the empire, with their families, who live in commodious and stately palaces, built in streets, with spacious courts shut up with strong and heavy gates. The second castle takes in a much smaller space of ground. It fronts the third, the residence of the emperor, and is enclosed by the first, but separated from both by walls, ditches, &c. Here are the stately palaces of some of the most powerful princes of the empire, the councillors of state, the prime ministers, chief officers of the crown, and such other persons as give immediate attendance on the emperor. The castle where the emperor himself resides is enclosed with a thick, strong wall of freestone, having bastions standing out, much after the manner of the European fortifications. On the top of this wall are erected several long buildings and square guard-houses, built in the form of towers, and several stories in height. Those on the side where the imperial residence is are all of freestone of an extraordinary size. It is adorned with a square tower, raised many stories high, adorned with beautiful bended roofs, gilt dragons at the top and corners, and many other fantastical ornaments. The second castle is very small, and more like a citadel; and the third lies on the side of the second, and is of much the same structure. In these two castles are bred the imperial princes and princesses. The rising ground behind the imperial residence is beautified with gardens and magnificent orchards. The palace itself is only of one story, but it is of great height, and contains many long galleries and spacious rooms, which, on removing the screens, may be narrowed or enlarged as occasion requires. The structure of all the interior apartments is fine, according to the fashion of the country; the ceilings, beams, and pillars are of cedar, or camphire, or a peculiar sort of wood, which runs into flowers and other curious figures, and is in some apartments covered only with a thin transparent layer of varnish, in others japanned, or curiously carved with birds and branched work neatly gilt. The floor is covered with the finest white mats, bordered with gold fringes or bands; and this is all the furniture to be seen in the emperor's palace. There are two strong rooms, in which are kept the imperial treasures. Besides being the residence of the court, and the seat of luxury, Jedo contains flourishing manufactures, and carries on an extensive commerce. From the combustible materials of which the houses are formed, it is liable to dreadful conflagrations. One that occurred in 1703 is supposed to have consumed 100,000 houses. Long. 140. E. Lat. 36. 30. N.

JEFREMOW, a city of the province of Tula, in Russia, the capital of a circle of the same name, on the river Metscha. It contains six wooden churches, and one of stone, 399 houses of different structure, and 2600 inhabitants. Long. 38. 54. E. Lat. 53. 40. N.

JEFFERSON, Thomas, one of the founders of American independence, and president of the United States, was born at Shadwell, in Albemarle county, Virginia, on the 2d of April 1743. His ancestors had at an early period emigrated to that province, and his father had been one of the commissioners for determining the boundary between Virginia and North Carolina. Having completed his education at William-and-Mary College, Williamsburg, he became a student of law under George Wythe, afterwards chancellor of the state of Virginia; and upon coming of age, he was admitted to the bar, appointed a justice of peace for the county in which he lived, and soon afterwards returned as one of its representatives in the provincial legislature.

But the position of public affairs early led him to contemplate questions far more comprehensive and important than any of those connected with the administration of his native state. As early as the year 1763 a spirit of opposition to the British government had manifested itself in the province, and continued gradually to increase, until, in 1769, it assumed the shape of a substantive determination not to import articles from the mother country. This resolution Mr Jefferson not only signed, but used all his influence to promote. In the beginning of 1773, a general system of resistance was first organized, by the formation of committees of correspondence in the different provinces. This plan, devised and matured by Jefferson, was eagerly adopted; and, when the measures of the British government in 1774 showed the increased necessity of opposing to them a united and resolute resistance, its benefits became strikingly apparent. The passing of the Boston port act, and the bills which immediately followed that measure, had, in the opinion of the colonists, filled up the measure of oppression and insult. The breach with the mother country daily became wider; and, as a crisis was evidently approaching, Jefferson's plan served not only to concentrate the general spirit of resistance, but also to give it a suitable direction. About this time he published a Summary View of the Rights of British America, which he intended as an exposition, to be laid before the sovereign, of the wrongs that country had suffered, and the sort of redress she was prepared to demand. For this publication, Lord Dunmore, the governor, threatened to prosecute him, on a charge of high treason, and also dissolved the legislature, which by its resolutions had sanctioned similar doctrines. In the following year, when the legislature was again assembled to consider the conciliatory propositions which had been sent out by the British ministry, Jefferson was appointed a member of the committee to whom these were referred, and he drew up the reply which was presented by that body; a document of great importance with reference to the history of the period to which it refers. But he had scarcely completed this task when he was called to perform a part on a wider field of action. The colonies having resolved to unite together, and send delegates to a general congress, Mr Jefferson took his seat as a member of that body, then assembled at Philadelphia, on the 21st of June 1775, and immediately became one of its most prominent members. In the following summer, when, from the tone of the debates in congress, and the general expression of public opinion, it appeared that the time had arrived for an entire and final separation from Great Britain, a committee was appointed to draw up a declaration to that effect. Of this committee Mr Jefferson was chairman, and, in conformity to the instructions of congress, he prepared the declaration of independence, which, after a few alterations, was adopted on the 4th of July 1776. This is by far the most memorable event in his life.

During the summer of this year, Mr Jefferson took an active part in the public business; but being obliged in the autumn to return to Virginia, he was, in his absence, appointed, in conjunction with Dr Franklin and Mr Deane, a commissioner to the court of France, for the purpose of arranging with the government of that country, treaties of alliance and commerce. Owing to ill health, and other causes, however, he declined the appointment, and shortly afterwards resigned his seat in congress; but being elected to the first legislature assembled under the new constitution of Virginia, he applied himself to introduce various changes and amendments into the laws and institutions of that state, particularly enactments for preventing the importation of slaves, destroying entails, abolishing the right of primogeniture, overthrowing the church establishment, and remodelling the whole of the statutory law. In June 1779 he was elected governor of Virginia, and reelected the following year. This was a season of imminent peril. The state, invaded on the north and the south, was ravaged by the troops of Tarleton and Arnold, and he himself was the object of especial pursuit. But amidst all the difficulties with which he was surrounded, Jefferson conducted the affairs of the state with so much prudence and energy, that, after the expiration of his term of service, the legislature passed an unanimous resolution, expressive at once of their gratitude, and of the high sense they entertained of his prudence, ability, and integrity. In June 1783, Mr Jefferson was again sent to congress as the delegate of Virginia, and, as a leading member of that body, was intrusted with the preparation of the address made by congress to General Washington, when he resigned his commission, and withdrew from public life. In May 1784, congress having decided that, in addition to Mr Adams and Dr Franklin, another minister plenipotentiary should be appointed, for the purpose of negociating treaties of commerce with the French government, Mr Jefferson was immediately elected to this office, and in the month of July sailed for France, where he arrived on the 6th of August. He remained in Europe until the 23d of November 1789, and, during his stay, visited Holland, the north of Italy, and the principal seaports on the southern and western coasts of France. He also crossed over to England, and, in concert with Mr Adams, endeavoured to negociate a commercial treaty with the British government; but their efforts were unavailing, and, after a fruitless visit of seven weeks, he returned to Paris. Whilst Mr Jefferson resided in France, he was not only engaged in various diplomatic negociations of importance to his own country, but was received with marked kindness by men of letters, science, and political distinction. He was likewise an eye-witness of the extraordinary occurrences in public affairs which took place in rapid succession towards the close of his sojourn in the French capital; he had become acquainted with many of the leading men of the national assembly, who were disposed to seek his advice, and place confidence in his opinions; and, as the representative of a free nation, he was an object of interest and attention to the principal actors in the new scenes which had opened upon France.

But his stay was not protracted till that fatal period which was darkened by the sanguinary excesses of popular frenzy; and the interest which he took in the French revolution was consequently warmed by the hope that a great people were about to shake off their fetters, and, by a peaceful but decisive effort, to establish rational liberty upon the solid foundation of improved institutions. In November 1789 he returned on leave of absence to the United States, and there accepted the office of secretary of state offered him by General Washington, instead of resuming his post as minister at the court of France. Whilst in the department of the state, Mr Jefferson laid down those general maxims relative to foreign intercourse, which have ever since been regarded with approbation by the American people, and developed those principles which, in his estimation, ought to govern the conduct of a neutral nation. He understood the true interests of his country: he felt that she required time to consolidate her new institutions, and to strengthen the foundations of the freedom she had conquered; and he laboured assiduously to impress his convictions on the minds of his countrymen. In December 1793, Mr Jefferson resigned his office, and having retired to private life, devoted himself to the education of his family, the cultivation of his estate, and the pursuit of those studies which he had long abandoned, but now resumed with fresh ardour. But he was not long permitted to enjoy the tranquillity of retirement. In September 1796, General Washington having made known to the people his wish not again to be a candidate for the presidency; and the two parties which had gradually grown up in the republic finding it impossible to unite, as in the case of Washington, in the choice of one individual to whom the administration of public affairs might by common consent be committed; Mr Adams was selected by the federalists, and Mr Jefferson by the democratic party, as their respective candidates; and, upon counting the votes, the former, in whose favour there appeared the higher number, was declared president, and the latter vice-president. At the next election, however, when again put forward as the popular candidate, he proved successful in his opposition to Mr Adams; and, although an accidental equality of votes between him and the person simultaneously chosen as vice-president raised a question which had not been provided for by the constitution, and thus gave his opponents an opportunity of contesting the validity of his election, yet, after a severe struggle, he was declared duly elected, and, on the 4th of March 1801, entered upon his first presidential term. The administration of Mr Jefferson embraced a long and interesting period in the history of the United States, and was distinguished by important measures, which contributed, in no inconsiderable degree, to promote the prosperity and increase the happiness of the free nation at the head of which he was placed. Under it various aggressions were promptly chastised; the attempt made by the agents of the Spanish government to obstruct the free navigation of the Mississippi was repelled; and the vast territory of Louisiana, affording an independent outlet for the western states, was purchased, and placed under the republican institutions of America. During the same period, the internal policy of the United States underwent important changes. Measures were adopted for liquidating the public debt; the judicial system was improved; a rigid economy controlled and regulated the public expenditure; all useless offices were abolished; and the president himself set the example of voluntarily relinquishing unnecessary power and patronage. The public approbation formed the best reward of these sacrifices; and hence, when Mr Jefferson's term of service had expired, he was again elected by a majority which had increased from eight votes to one hundred and forty-eight. In his inaugural address, delivered on the 4th of March 1805, he declared his firm determination to continue to act upon those principles on which he believed it to be his duty to administer the affairs of the commonwealth, and which had already been sanctioned by the unequivocal approbation of the country. But he had scarcely entered upon office when an event occurred which seemed calculated to disturb the domestic tranquillity of the United States, if not to endanger the stability of the union itself. This was the conspiracy of Colonel Burr, a man of an ardent and ambitious character, who, disappointed formerly in attaining the first office of the government when it seemed within his grasp, and afterwards superseded in the second by the election of Mr Clinton, now sought, by desperate means, either to establish a new republic in the Spanish provinces of the west, or to break up the federal union in his own country. But his scheme was discovered, and although, when apprehended and brought to trial on a charge of treason, he obtained a verdict of acquittal, yet enough came out in evidence to show the government the extent of its danger, and to indicate the measures necessary to prevent its recurrence. At this period, too, the foreign relations of the United States became greatly embarrassed, in consequence of the war which raged in Europe. Nearly the whole of their revenue depended on commerce; and on this serious aggressions had been made by both the belligerent powers, France and Britain; whilst the right of search claimed by the latter was resented, as at once contrary to the public law of nations, insulting to the American flag, and inconsistent with free navigation. In this view, the natural and obvious remedy was a declaration of war. But, as it was conceived that the interests and situation of America required the previous trial and failure of all other means of obtaining justice, an embargo was resorted to, and a measure for establishing one passed congress on the 22d of December 1807, in consequence of the recommendation of the president. After this embargo had existed a year, however, overtures were made by the British government, indicating a disposition to abate somewhat of its pretensions; and as these had been preceded by the recall of some of those orders in council to which the Americans most strongly objected, an accommodation was effected without difficulty, because in fact the non-intercourse system had proved more prejudicial to the commercial interests of the United States than to those of Great Britain.

Affairs were in this situation when, on the 3d of March 1809, Mr Jefferson's second term of office expired, and with it also terminated his political career. He had now attained the sixty-fifth year of his age, and had for forty years been almost without interruption engaged in the most arduous public duties. He had passed with honour and credit through the various stations to which the service of his country had called him, and he now resolved to quit the scene where he had so long acted a prominent part, whilst yet unoppressed by the infirmities of age, and to pass the evening of a busy life in the calmness of domestic retirement. From this time until his death, which took place on the 4th of July 1826, he resided chiefly at his favourite retreat, Monticello; sometimes occupying his time with publications of his private correspondence, and at others connecting himself with rising institutions formed to promote the advancement of science, literature, or taste. He was sought out in his retirement by strangers of all nations who visited America, and also by the natives of every part of his own country, who regarded him as "their guide, philosopher, and friend." His residence was the abode of dignified ease and unostentatious hospitality; in the calm enjoyments of Monticello, he forgot both the toils and the dangers of his long political career; he took the deepest interest in everything which seemed calculated to advance the improvement or increase the happiness of mankind; at once practical and benevolent, he was constantly studying the welfare of his fellow-creatures, and endeavouring to promote every plan which tended to produce or increase it. Amongst his labours of this kind, the most prominent consisted in the exertions he made for the improvement of education in Virginia, by the establishment of an university at Charlottesville, a town at the foot of the mountain where he resided. This institution, commenced by his own private donations, and those which he succeeded in obtaining from his friends, received the sanction of the legislature; Mr Jefferson's plans, having for their object to combine elegant learning with strictly useful knowledge, were approved of; he himself was appointed rector of the new university; and from this time forward he devoted himself to consolidate the establishment which he had founded. Indeed all his thoughts and means were employed to insure its success.

"Thus," says an American biographer, "glided on the evening of Mr Jefferson's patriotic and benevolent life; as age wore gradually away the energies of his body, his mind shone with intelligence undiminished; and his efforts and desires for the progress of human happiness and knowledge knew no change. Years, however, had crowded upon him; and when the increase of infirmities at length prevented him leaving his chamber, he remarked to the physician who sought to assist him by the aid of his art, that 'the machine had worn out, and could go on no longer.' During the spring of 1826, he had suffered from increasing debility; but it was not until the 26th of June that he was obliged to confine himself to his bed. The strength of his constitution, and freedom from bodily pain, for a short time encouraged the hope that this confinement would be only temporary; but his own conversation showed that he did not himself so regard it. 'Do not imagine,' he said to those around him, 'that I feel the smallest solicitude as to the result. I do not indeed wish to die, but I do not fear to die.' His temper retained all its usual cheerfulness and equanimity; his only anxiety seemed to be for the prosperity of the university, and he expressed strongly his hopes that the state would not abandon it: he declared that if he could see that child of his old age fairly flourishing, he was ready to depart, to say 'nunc dimittis domine,' a favourite quotation with him. On the 2d of July he appeared free from disease, but his weakness was such that his physicians expressed a doubt whether his strength would prove sufficient to restore him. Conscious himself that he could not recover, and without any bodily or apparently mental pain, he calmly gave directions relative to his interment, which he requested might be at Monticello, without parade or pomp; he then called his family around him, and conversed separately with each of them; to his beloved daughter, Mrs Randolph, he presented a small morocco case, which he requested her not to open till after his death. When the sad limitation had expired, it was found to contain an affectionate poetical tribute to the virtues of her from whom he was thus torn away. He desired, if any inscription were placed on his tomb, he should be described only as 'the author of the declaration of independence, of the statutes of Virginia for religious freedom, and the father of the university.' On Monday, the following day, he inquired of those around him with much solicitude what was the day of the month; they told him it was the 3d of July. He then eagerly expressed his desire that he might be permitted to live to another day, to breathe the air of the fiftieth anniversary of the declaration of independence. His wish was granted: the morning of the 4th of July 1826 found him still living; and after declaring himself gratified by the affectionate solicitude of his family and servants, and having distinctly articulated these words, 'I resign myself to my God, and my child to my country,' he gradually expired without a murmur or a groan."

At the time of his death Mr Jefferson had just entered the eighty-fourth year of his age. In person he was above six feet in height, and, though thin, erect and well formed. His complexion was fair, his forehead broad, and his face of a square form, with a thoughtful expression. His address was cordial, and his manner simple, cheerful, and unassuming, yet mingled with a certain degree of native dignity; in his disposition he was full of liberality and benevolence; in his temper he displayed the greatest equanimity, never being known to give way to passion, nor, even during the excitement of political contentions, to indulge in angry or vindictive feelings. His attachment to his personal friends was warm and stedfast; to them he communicated without reserve all that he thought or felt; in regard to them he exercised no diplomatic caution, nor entertained any ungenerous distrust; and he had his reward in that unflinching support which he received from them on every emergency. His application was constant and severe; and his habits were so exact, that in a cabinet abounding with papers, all were arranged in such a manner that any one might be instantly found. Considered intellectually, however, Mr Jefferson does not appear to us to occupy the distinguished rank which has been generally assigned to him by his countrymen, particularly by his eloquent eulogist Mr Webster. On the contrary, he seems to have been one of those men of plain, practical good sense, calm temperament, methodical habits, and persevering application, who make the most of their faculties, and are, upon the whole, much better fitted to excel in the conduct of business than to obtain distinction in pursuits of a higher order, or to stamp the impression of their genius upon the science, the literature, the philosophy, or the legislation of their time. Jefferson was perhaps at the head of the class to which he belonged, but that class was not a high one; and, in truth, he had always been more remarkable for the share which he took in the early formation of the American republic, than for any very predominant superiority of understanding. (*American National Portrait Gallery*, part xxiii.; Jefferson's *Memoirs*, vol. i.; *Edinburgh Review*, vol. xxxi. p. 139; *North American Review*, No. 86.) (A.)

JEFFREYS, Sir George, Baron Wem, commonly called *Judge Jeffreys*, was the sixth son of Mr John Jeffreys, of Acton, in Denbighshire; and was educated at Westminster School, whence he removed to the Inner Temple, where he applied himself to the study of the law. Alderman Jeffreys, who was probably related to him, introduced him among the citizens of London; and being a merry bottle companion, he soon came into great business, and was chosen their recorder. He was afterwards chosen solicitor to the Duke of York; and in 1680 he was knighted, and made chief justice of Chester. At length, resigning the recordership, he obtained the post of chief justice of the king's bench, and, soon after the accession of James II. the great seal. During the reign of King Charles II. he showed himself a bitter enemy to those dissenting ministers who, in that time of persecution, were tried by him. He was one of the principal advisers and promoters of all the oppressions and arbitrary measures carried on in the reign of James II.; and his sanguinary and inhuman proceedings against Monmouth's unhappy adherents in the west will for ever render his name infamous. Whenever the prisoner was of a different party, or whenever he could please the court by condemning him, instead of appearing, according to the duty of his office, as his counsel, he would scarcely allow him to speak for himself, but would load him with the grossest and most vulgar abuse, browbeat, insult, and turn to ridicule the witnesses that spoke in his behalf, and even threaten the jury with fines and imprisonment if they made the least hesitation about bringing in the prisoner guilty. Yet it is said, that when he was in temper, and matters perfectly indifferent came before him, no one became a seat of justice better. Nay, it even appears, that when he was under no state influence, he was sometimes inclined to protect the natural and civil rights of mankind, of which the following instance has been recorded. The mayor and aldermen of Bristol had been used to transport convicted criminals to the American plantations, and sell them by way of trade. This turning to good account, when any pilferers or petty rogues were brought before them, they threatened them with hanging, and then some officers who attended earnestly persuaded the ignorant, intimidated creatures to beg for transportation, as the only way to save their lives; and in general the advice was followed. Then, without more form, each alderman in course took one, and sold him for his own benefit; and sometimes warm disputes arose between them about the next turn. This infamous trade, which had been carried on for many years, coming to the knowledge of the lord chief justice, he made the mayor descend from the bench, and stand at the bar in his scarlet and fur, with his guilty brethren the aldermen, and plead as common criminals. He then obliged them to give securities to answer informations; but the proceedings were stopped by the Revolution. However, the brutality which Jeffreys commonly showed on the bench, where his voice and visage were equally terrible, at length exposed him to a severe mortification. A scrivener of Wapping having a cause before him, one of the opponent's council said he was a strange fellow, and sometimes went to church, and sometimes to conventicles, and it was thought he was a trimmer. At this the chancellor fired. "A trimmer!" said he; "I have heard much of that monster, but never saw one. Come forth, Mr Trimmer, and let me see your shape." He then treated the poor fellow so roughly, that, on his leaving the hall, he declared he would not undergo the terrors of that man's face again to save his life, and that he should certainly retain the frightful impressions of it as long as he lived. Soon afterwards, when the Prince of Orange landed, the lord chancellor, dreading the public resentment, disguised himself in a seaman's dress in order to leave the kingdom, and was drinking in a cellar, when this scrivener, coming into the cellar, and seeing again the face which had filled him with such horror, started; upon which Jeffreys, fearing he was known, feigned a cough, and turned to the wall with his pot of beer in his hand. But Mr Trimmer going out, gave notice that he was there; and the mob rushing in, seized him, and carried him before the lord mayor, who sent him with a strong guard to the lords of the council, by whom he was committed to the Tower, where he died in 1689. It is remarkable, that the late Countess of Pomfret met with very rude insults from the populace on the western road, solely because she was grand-daughter to the inhuman Jeffreys.

JEGHEDERPOOR, a town of Hindustan, in the province of Gundwana, twenty miles south from Bustar. Long. 82. 21. E. Lat. 19. 26. N.

JEHANABAD, a town of Hindustan, belonging to the Mahrattas, in the province of Khandesh, three miles south from Boorhanpoor. Long. 76. 21. E. Lat. 21. 18. N.

JEHENABAD, a town of Hindustan, in the province of Bahar, thirty-three miles south by west from Patna. Long. 82. 5. E. Lat. 25. 13. N.

JEHOVAH, one of the scriptural names of God, signifying the Being who is self-existent and gives existence to others. So great a veneration had the Jews for this name, that they discontinued the custom of uttering it, and hence its true pronunciation was forgotten. They called it *tetragrammaton*, or the name of four letters; and believed that whoever knew the true pronunciation of it could not fail to be heard by God.

JEHUNGSEAL, a small town of the Afghan territories, in the province of Mooltan, thirty miles north-east from the city of Mooltan. Long. 71. 40. E. Lat. 30. 54. N.

JEJUNUM, the second of the small guts, so called from the Latin *jejunus*, hungry; because it was always found empty. See ANATOMY.

JEJURRY, a Mahratta town of Hindustan, in the province of Bejapoor. This place is noted for a fine Hindu temple, built of hewn stone, and dedicated to an incarnation of Mahadeva or Siva, under the form of Khandeh Row, which he assumed to destroy an enormous giant named Manimal. The temple has very ample revenues, about L.6000 annually being expended on account of the idol, for whom horses and elephants are maintained; and who, with his spouse, is washed every day in rose and Ganges water, which has to be brought a distance of 1000 miles. About 250 dancing girls are attached to the establishment, with many Brahmins, and beggars innumerable. The revenues are derived from the donations of the pious, consisting of houses, lands, and money. This is a noted place for penance; and, at a particular season of the year, a number of persons, in order to expiate their sins, undergo the penance of swinging on a kind of gibbet, suspended by hooks passed through the fleshy part of the back. Twenty-eight miles south-east from Poonah. Long. 74. 17. E. Lat. 18. 16. N.

JELASIR, a town of Hindustan, in the province of Agra, twenty-eight miles north-east from the city of Agra. Long. 78. 15. E. Lat. 27. 30. N.

JELATMA, a city of the Russian province of Tambow, the capital of a circle of the same name, on the river Oka. It is an ancient and large place, containing eight stone and two wooden churches, several public buildings, and 778 houses, with 5800 inhabitants. It has considerable manufactures of linen and sail-cloth. Long. 42. 28. E. Lat. 55. 5. N.

JELEZ, a town of the province of Orel, in Russia, the capital of a circle of the same name, on the river Alt. It is a very ancient city, containing twelve stone and two wooden churches, 1290 houses, and 7950 inhabitants. Long. 38. 33. E. Lat. 52. 38. N.

JELEZENKA, a small river in the government of Irkoutsk, in Asiatic Russia, which falls into the Irtysch.

JELEZENSKAIA-CREPOST, a port of Asiatic Russia, on the right bank of the Irtysch, in the government of Tobolsk. It contains a church and 130 houses, and is surrounded by a fertile country very carefully cultivated. It was formerly built of wood, but has since been constructed more regularly of earth. Lat. 53. 51. N.

JELISAWETGRAD, a city of Russia, in the province of Cherson, the capital of a circle of the same name. It stands on a beautiful plain on the banks of the river Ingul. It is fortified, and defended by a strong citadel. It contains 1500 houses, and 12,000 inhabitants, consisting of various tribes and countries, attracted by large fairs held there in the autumn. Long. 32. 22. E. Lat. 48. 30. N.

JELLALABAD, a town of Hindustan, in the province of Delhi, and district of Bareilly, forty-four miles south by east from Barielly. Long. 79. 37. E. Lat. 27. 45. N.

JELLALABAD, a town of Afghanistan, in the province of Cabul, situated in the rich plain of Jellalabad. It was formerly of great note, and is still of considerable importance. It has a public market, and the adjacent district produces a coarse sugar. Seventy-three miles east-south-east from the city of Cabul. Long. 69. 46. E. Lat. 34. 6. N.

JELLALÆAN, or GELALÆN *Calendar, Epoch, and Year*. See CALENDAR and CHRONOLOGY.

JELLY, a form of food or medicine, prepared from the juices of ripe fruits, boiled to a proper consistence with sugar; or the strong decoctions of the horns, bones, or extremities of animals, boiled to such a degree as to be stiff and firm when cold, without the addition of any sugar.

JELPESH, a town of the province of Bengal, and district of Ringpoor, sixty-five miles north-north-west from Ringpoor. Long. 88. 25. E. Lat. 26. 30. N.

JEMAULABAD, a town and fortress in the south of India, province of Canara, which was originally called Narasingha Augady. The first, which was built by Tippoo, stands on the summit of an immense rock, which may be deemed impregnable, as it is wholly inaccessible except by one narrow way. The nature of the access to it, however, renders the approach to it in the face of an enemy nearly as difficult as the ascent; so that a very small body of men with artillery are adequate to blockade a strong garrison, which renders the place of little use, excepting as a safeguard for treasure or records. After the fort was built by Tippoo, he placed in it a khiladar or commandant, with a garrison of 400 men; and the town at that time contained 1000 houses, and carried on a considerable trade. On the invasion of Mysore, the Coorg rajah destroyed the town, and carried away half the inhabitants; the remainder made their escape into the woods, and only about twenty houses have since been rebuilt. After the fall of Seringapatam, it sustained a siege of six weeks from the British, when, being bombarded, it was taken, and, the commander having poisoned himself, his principal officers were hanged. It was afterwards surprised and taken by a band of insurgents or plunderers, when it was reduced, after a blockade of three months, and all that did not escape were summarily executed. The surrounding country is woody. Long. 75. 24. E. Lat. 13. N.

JEMAULNAIG, a town of Hindustan, in the Balaghaut ceded territories, situated on the north side of the Pennar River, forty-one miles north-west from Cuddapah. Long. 78. 28. E. Lat. 14. 48. N.

JEMLAH, a small district of Hindustan, situated between the thirtieth and thirty-first degrees of north latitude. It was formerly an independent state, but is now tributary to the rajah of Nepaul. It is said to be nearly of the same extent as that of Nepaul, but to be more contiguous to the great Himalaya ridge of mountains, and more chequered with low hills. It produces a species of rice which is adapted to the climate of northern countries. Its capital is called Chinnochin, but has not been visited by Europeans.

JEMMAPPES, a large village of the Netherlands, in the province of Henegau, and circle of Mons. It stands on the river Haine, and contains 2838 inhabitants, who are busily occupied in the numerous coal-mines and the mill-stone quarries with which it abounds. It is remarkable for the decisive battle fought there in 1792, when the French, commanded by Dumouriez, defeated the Austrian army under Clairfayt, which led to the subjugation of Brussels and the rest of Flanders.

Jena || Jenyns.

JENA, a city of the grand duchy of Saxe-Weimar, in Germany, the capital of a circle of the same name. It stands in a beautiful valley, through which the river Saale runs, and is surrounded with hills, whose sides are covered with vineyards. It contains three Lutheran and one Catholic church, three hospitals, and 795 houses, with about 5500 inhabitants. It is the seat of the higher courts of law of the duchy, and of some of the revenue boards. Its chief celebrity has arisen from its university, founded in 1558. The number of professors is very great, and among them have always been some of the highest literary characters in Germany. It possesses institutions for education in physic, in mathematics, in medicine, in midwifery, in anatomy, mineralogy, surgery, veterinary practice, and a public library of more than 30,000 volumes. In consequence of a suspicion of the propagation of revolutionary principles, the number of students have, since 1818, been diminished, and now amount only to about 550. Jena is celebrated for the battle fought near it in October 1806, when Bonaparte vanquished and dispersed the Prussian army commanded by the Duke of Brunswick.

JENEAHGUR, called also Jagneh, a town, and also a strong and celebrated fortress, of Hindustan, province of Bejapoor, situated upon a rock with an extensive tableland. It was built about the year 1443, by Mulik al Tajur, generalissimo of the Bhamenee sultan. It afterwards came into the possession of the Bejapoor dynasty, from whom it was taken by the Moguls, and was the chief station of Aurungzebe's army during his war against the Mahratta chief Seraje. It now belongs to the Mahrattas. Long. 73. 45. E. Lat. 20. 15. N.

JENIDSCHE-Bardar, a town of European Turkey, in the circle of Salonica. It is an open place, on the river Bardar, with several mosques and Greek churches, and charitable institutions. It contains 6000 inhabitants, who manufacture cotton goods extensively.

JENJAPOOR, a town of Hindustan, province of Bahar, and district of Tyrhoot, eighty miles north-east from Patna. Long. 86. 15. E. Lat. 26. 14. N.

JENKINS, Sir Leoline, a civilian and statesman of considerable note, born in Glamorganshire about the year 1623. Having become obnoxious to the parliament during the civil war, by adhering to the king's cause, he consulted his safety by flight; but he returned at the restoration, was admitted an advocate in the court of arches, and succeeded Dr Exton as judge. When the queen-mother Henrietta died at Paris in 1669, her whole estate, real and personal, was claimed by her nephew Louis XIV.; upon which Dr Jenkins' opinion being called for and approved, he proceeded to Paris, accompanied by three others who were joined with him in a commission, and recovered her effects; a service for which he received the honour of knighthood. He officiated as one of the mediators at the treaty of Nimeguen, and was afterwards made a privy councillor and secretary of state. He died in 1685, and bequeathed his whole estate to charitable uses. Dr Jenkins was so great a benefactor to Jesus College, Oxford, that he is generally looked upon as the second founder. All his letters and papers were collected and printed in 1724, in two vols. folio.

JENTACULUM, among the Romans, a morning refreshment like our breakfast. It was exceedingly simple, consisting, for the most part, of bread alone; but labouring people had something more substantial, to enable them to support the fatigues of their employment. The Greeks distinguished this morning meal by the several names of *ἀριστον*, *ἀκρατισμος*, or *ἀκρατισμα*, though *ἀριστον* is generally applied to dinner.

JENYNS, Soame, a distinguished English writer, was born in Great Ormond Street, London, in the year 1704. Sir Roger Jenyns, his father, was descended from the family of the Jenyns of Churchill in Somersetshire. The country residence of Sir Roger was at Ely, in the isle of the same name, where he turned his attention to such kinds of business as rendered him most beneficial to his neighbours, and for his amiable deportment had the honour of knighthood conferred upon him by William III. His mother, a lady of rank, learning, and piety, superintended his education till it became necessary to place him under a tutor, by whom he was instructed in the rudiments of language, and such other branches of knowledge as were suited to his years.

In the year 1722, he was admitted into St John's College, Cambridge, under Dr Edmondson, who was at that time one of the leading tutors of the college. Here his diligence and regular deportment did him great honour, and the strict discipline observed in the college was perfectly agreeable to his natural inclinations. After quitting the college, he fixed his winter residence in London, but lived in the country during the summer season, being chiefly employed in the prosecution of studies of a literary kind. His first publication, a poetical essay on the art of dancing, appeared without his name in 1727; but he was soon discovered, and it was considered as a presage of his future eminence. Soon after the death of his father, he was, in 1742, chosen one of the members of parliament for the county of Cambridge; and from this period he retained his seat in the House of Commons until the year 1780. The high opinion entertained by his constituents, of his parliamentary conduct, may be learned from the unanimity of their choice; for he never experienced opposition but on one occasion. He was chosen one of the commissioners of the Board of Trade and Plantations in 1755, an office which he retained until an alteration was made in the constitution of it by authority of parliament. He was married, first, to the only daughter of Colonel Soame, of Dereham in Norfolk, who died without issue; and afterwards to the daughter of Mr Henry Gray, of Hackney, who survived him. He died of a fever, after a few days' illness, on the 18th of December 1787, leaving no issue. His temper was mild and gentle, and it was his earnest wish to avoid giving offence to any; yet he made such liberal allowances for diversities of temper, that he was very rarely offended with others. He was punctual in the discharge of the duties of religion, both in public and private; professing to be better pleased with the government and discipline of the church of England than of any other in Christendom, but at the same time considering these as capable of important alterations and amendments. He possessed a vein of lively and genuine wit, which he never made use of to wound the feelings of others, but was rather offended with those who did. He felt most sensibly for the miseries of others, and used every means in his power to relieve them. His indigent neighbours in the country he viewed as part of his family, and in this light he considered them as entitled to his care and protection. As an author, Soame Jenyns deserves a place amongst those who have excelled; and, as a writer of prose, he ranks with the purest and most correct of the English language. His first publication was his Free Inquiry into the Nature and Origin of Evil, on account of which he was severely censured; but, in a preface to the second edition, he vindicated it against all the strictures which had been made upon it, with that temper and moderation which so eminently distinguished him. His view of the Internal Evidences of the Christian Religion was published without his name in the year 1776; it gave delight and satisfaction to many eminent judges, and made converts of many who had previously been infidels. His works were published at London in 1790, in four vols. 8vo, with an account of his life by Mr Cole.

JEOFAILE (compounded of three French words, *J'ay faille,* I have failed), a term in law, used to indicate an oversight in pleading or other proceeding at law.

The showing of these defects or oversights was often practised by the counsel formerly; and when the jury came into court in order to try the issue, they said, This inquest you ought not to take; and after verdict they would say to the court, To judgment you ought not to go. But several statutes have been made to avoid the delays occasioned by such suggestions; and a judgment is not now to be stayed after verdict for a mistake in the Christian or surname of either of the parties, or in a sum of money, or in the day, month, year, &c. where the same are rightly named in any preceding record.

JEPHTHAH, judge of Israel, and successor to Jair in the government of the people, was a native of Mizpeh, and the son of one Gilead by a woman of indifferent reputation. This Gilead having married a lawful wife, and had children by her, drove Jephthah from his father's house, saying that he should not be heir with them. Jephthah retired into the land of Tob, and there became captain of a band of thieves. At that time the Israelites beyond Jordan, seeing themselves pressed by the Ammonites, came to desire assistance from Jephthah, and to request that he would take upon him the command. Jephthah at first reproached them with the injustice which they had done him, or at least which they had not prevented, when he was forced from his father's house. But as these people were earnest and pressing in their request, he told them that he would succour them, provided at the end of the war they would acknowledge him as their prince. This they consented to, and promised with an oath. Jephthah having thus been acknowledged prince of the Israelites in an assembly of the people, was filled with the spirit of God, and began to get his troops together; and for this purpose he travelled over all the land which the children of Israel possessed beyond Jordan. At the same time he made a vow to the Lord, that if he were successful against the Ammonites, he would offer up as a burnt-offering whatever should first come out of his house to meet him. The battle being fought, Jephthah proved victorious, and ravaged all the land of Ammon. But as he returned to his house, his only daughter came out to meet him, with timbrels and with dances; whereupon Jephthah tore his clothes, saying, "Alas, my daughter, thou hast brought me very low, for I have made a vow unto the Lord, and cannot fail in the performance of it." His daughter answered, "My father, if thou hast made a vow unto the Lord, do with me as thou hast promised; grant me only the favour that I may be at liberty to go up to the mountains, and there for two months bewail my virginity with my companions." Jephthah granted her this liberty; and at the expiration of two months he offered up his daughter as a burnt-offering, agreeably to his vow. Meanwhile, the Ephraimites, jealous of the victory obtained by Jephthah over the Ammonites, passed the river Jordan in a tumultuous manner, and complaining to Jephthah that he had not invited them to this war, threatened to set fire to his house. Jephthah answered them, that he had sent to desire their assistance; but observing that they did not come, he put his life in the hands of God, and hazarded a battle. The Ephraimites not being satisfied with these reasons, Jephthah assembled the people of Gilead, gave them battle, and defeated them; so that of the tribe of Ephraim there were forty-two thousand men killed on that day. We know nothing more concerning the life of Jephthah, except that he judged Israel during six years, and was buried in a city of Gilead.

JERBOA, a species of quadruped belonging to the genus *dipus*, and resembling, in some of its characters, the mouse tribe. See Mammalia.

JEREMIAH (*the Prophecy of*), a canonical book of the Old Testament. This divine writer was of the race of the priests, the son of Hilkiah of Anathoth, of the tribe of Benjamin. He was called to the prophetic office when very young, about the thirteenth year of Josiah, and continued in the discharge of it for about forty years. He was not carried captive to Babylon with the other Jews, but remained in Judæa to lament the desolation of his country. He was afterwards a prisoner in Egypt, with his disciple Baruch, where it is supposed he died at a very advanced age. Some of the Christian fathers tell us he was stoned to death by the Jews for preaching against their idolatry; and others say he was put to death by Pharaoh Hophrah, because of his prophecy against him. Part of the prophecy of Jeremiah relates to the time after the captivity of Israel and before that of Judah, and part of it was written in the time of the latter captivity. The prophet lays open the sins of Judah with great freedom and boldness, and reminds them of the severe judgments which had befallen the ten tribes for the same offences. He warmly laments their misfortune, and recommends to them a speedy reformation. Afterwards he predicts the grievous calamities which were approaching, particularly the seventy years captivity in Chaldæa. He also foretells their deliverance and happy return, and the recompense which Babylon, Moab, and other enemies of the Jews, should in due time meet with. There are likewise several intimations in this prophecy concerning the kingdom of the Messiah, and several remarkable visions, and types, and historical passages, relating to those times. St Jerome has observed respecting this prophet, that his style is more easy than that of Isaiah and Hosea; that he retains something of the rusticity of the place where he was born; but that he is very learned and majestic, and equal to those two prophets in the sense of his prophecy.

JERICHO, or Hierichus, in *Ancient Geography*, a city of Judæa, situated between Jordan and Jerusalem, at the distance of 150 stadia from the latter, and sixty from the former. Josephus says, "The whole space from Jerusalem is desert and rocky, and equally barren and uncultivated from Jericho to the Lake Asphaltites; yet the places near the town and above it are extremely fertile and delicious, so that it may justly be called a divine plain, surpassing the rest of the land of Canaan, no unfruitful country, and surrounded by hills in the manner of an amphitheatre. The place is now called *Raha*, and, according to Volney, is situated "in a plain six or seven leagues long by three wide, around which are a number of barren mountains, which render it extremely hot." Here was formerly cultivated the balm of Mecca. From the description of the Hadjis, this is a shrub similar to the pomegranate tree, with leaves like those of rue; it bears a pulpy nut, in which is contained a kernel that yields the resinous juice which we call *balm* or *balsam.* At present there is not a plant of it remaining at Raha; but another species is to be found there, called *zakkoun*, which produces a sweet oil, also celebrated for healing wounds. This zakkoun resembles a plum-tree; it has thorns four inches long, with leaves like those of the olive-tree, but greener, and more narrow, as well as prickly at the end; its fruit is a kind of acorn, without a calyx, under the bark of which is a pulp, and then a nut, the kernel of which gives out an oil that the Arabs sell very dear. This constitutes the sole commerce of Raha, which is no more than a ruinous village.

JEROME, St, in Latin *Hieronymus*, a celebrated doctor of the church, and the most learned of all the Latin fathers, was the son of Eusebius, and was born at Stridon, a city of the ancient Pannonia, about the year 340. He studied at Rome under Donatus, the learned grammarian. After having received baptism, he proceeded into Gaul, and there transcribed St Hilary's book *De Synodis*. He then went into Aquilcia, where he contracted a friendship with Heliodorus, who prevailed on him to travel with him into Thrace, Pontus, Bithynia, Galatia, and Cappadocia. In 372 St Jerome retired into a desert in Syria, where he was persecuted by the orthodox of Melitius's party for being a Sabellian, because he made use of the word *hypostasis*, which had been employed by the council of Rome in 369. This obliged him to go to Jerusalem, where he applied himself to the study of the Hebrew language, in order to acquire a more perfect knowledge of the Holy Scriptures; and about this time he consented to be ordained, on condition that he should not be confined to any particular church. In 381, he went to Constantinople to hear Gregory Nazianzen, and the following year returned to Rome, where he was made secretary to Pope Damasus. He then instructed many Roman ladies in piety and the knowledge of the sciences, which exposed him to the calumnies of those whom he zealously reproved for their irregularities; and Pope Siricius not having all the esteem for him to which his learning and virtue justly entitled him, this learned doctor left Rome, and returned to the monastery of Bethlehem, where he employed himself in writing against those whom he called heretics, especially Vigilantius and Jovinian. He had a quarrel with John of Jerusalem and Rufinus about the Origenists. St Jerome was the first who wrote against Pelagius. He died on the 30th of September 420, at about eighty years of age. There have been several editions of his works; the last, which is that of Verona, is in eleven vols. folio. His principal works are, 1. A Latin version of the Holy Scriptures, distinguished by the name of the *Vulgate;* 2. Commentaries on the Prophets, Ecclesiastes, St Matthew's Gospel, and the Epistles to the Galatians, Ephesians, Titus, and Philemon; 3. Polemical treatises against Montanus, Helvidius, Jovinian, Vigilantius, and Pelagius; 4. Letters; 5. A treatise on the lives and writings of the ecclesiastical authors who had flourished before his time. The style of St Jerome is lively and animated, sometimes rising to the sublime.

Jerome *of Prague*, so called from the place of his birth in Bohemia. He was neither a monk nor a clergyman, but had received a learned education. Having embraced the opinions of John Huss, he began to propagate them in the year 1480. In the mean time the council of Nice kept a watchful eye over him, and, considering him as a dangerous person, cited him to appear before them and give an account of his faith. In obedience to this citation, he went to Constance; but on his arrival, in 1415, finding Huss in prison, he set out for his own country. Being seized on the way, imprisoned, and examined, however, he was so intimidated that he retracted, and pretended to approve of the condemnation of the opinions of Wickliff and Huss. But he recanted his retractation, which, on the 26th of May 1416, he condemned in these terms: "I am not ashamed to confess here publicly my weakness. Yes, with horror I confess my base cowardice. It was only the dread of the punishment by fire which drew me to consent, against my conscience, to the condemnation of the doctrine of Wickliff and Huss." Accordingly sentence was passed on him, in pursuance of which he was delivered to the secular arm, and burned, in 1416. He was a person of great parts, learning, and elocution.

JERONYMITES, Hieronymites, a denomination given to various orders or congregations of religious persons, otherwise called *Hermits of St Jerome*.

JERSEY, one of a group of islands, forming part of the ancient duchy of Normandy, but now considered as a portion of the county of Hampshire in England, for some few legal purposes. It is about six leagues from the French, and twenty-three from the English coast. It is nearly twelve miles in length from east to west, and in no part more than seven miles in breadth. The square extent is sixty-three miles, or about 40,000 English acres. The shore is indented with numerous bays; but they are very difficult of access, from the rapidity of the tide, which, among the rocks that surround the island, causes eddies of great but variable velocity. The island is protected by appropriate fortifications, and in time of war is commonly provided with a sufficient military force, besides a well-disciplined militia, to defend it from sudden attacks. The face of the island is rather hilly, with rich, well-watered valleys between the respective ranges; the slope is towards the south; and, though the tops of the hills are almost barren, yet the soil in the lower parts is a rich and well-cultivated alluvium. The climate is mild and uniform, frosts being rare in winter, and the air being tempered by the sea-breezes in the summer. Though fertile, the island does not grow sufficient corn for the sustenance of the dense population; but it yields a surplus of fruit, of cider, and of potatoes; and, besides, sends yearly to England some hundreds of the peculiar race of cows which, like those of Guernsey and Alderney, are esteemed for the great quantity rather than the good quality of the milk which they yield. The chief trade of the island is the Newfoundland fishery, for which several ships are equipped and annually despatched. Formerly a great contraband trade was carried on; and in time of war the business of privateering was extensively followed. The island is governed by a local legislature and a distinct judicature, under the ultimate control of the king in council. The ancient Norman laws are still in force, and the greater part of the inhabitants retain, and among themselves use, the language of the country from which they originated. The church of England is the established religion, and is under the ecclesiastical direction of the Bishop of Winchester. There are several of the other protestant sects, who support their own religious institutions. Though easily defended as long as England has a superior naval force to succour it, Jersey has always been deemed a desirable possession by France. Several attacks have been projected, and one actually made in 1781, which was at first successful, but ultimately repelled by a body of troops under the brave Major Pierson, who was unfortunately killed in the action. In an attempt two years before, the French were intercepted by an English squadron, and destroyed before they could land any troops. The chief town is St Hilliers; another town, St Aubins, is smaller; both the harbours are dry at low water. The population amounts to upwards of 29,000, being the most dense of any in the British dominions.

JERSEY, New, one of the thirteen original states of the American union, is bounded on the north and north-east by New York, on the east and south-east by the Atlantic Ocean, on the south-west by Delaware Bay, and on the west by Pennsylvania. The extreme length directly from north to south is one hundred and seventy miles, the mean breadth is about forty-six miles, and the whole state contains an area of 7820 square miles.

The surface of the country presents every variety, but three marked divisions may be particularised; first, a sandy or marine section; secondly, a hilly or middle section; and, thirdly, a mountainous section. The first occupies nearly one half of the area of the state. A line from the mouth of Shrewsbury River to Bordentown will very nearly separate the alluvial from the hilly region. Between this limit and the continuation of the blue ridge, the state is beautifully variegated by rich and bold scenery. From the north to the south a succession of mountains, and lesser hills and heights, interspersed with plains, stretch out, each occupying a distinct and well-defined region. The mountainous portion of New Jersey is the extreme northern part of the state, composed of the counties of Warren and

Sussex. The elevation of the different sections has not been very accurately determined, but the higher valleys of the latter county must be from 800 to 1000 feet above the level of the sea. The descent from the mountain to the hilly region is abrupt, as by the steps of a stair. A remarkable difference of temperature is experienced in the space of less than two and a half degrees of latitude. The alluvial plains of the southern section have a mild or rather tropical climate, resembling the eastern part of Virginia, and admit of the cultivation of cotton; whilst in the counties of Sussex and Warren it is more various, and, though salubrious enough, is in general less mild.

The principal internal waters are Second River, Hackinsack, Passaic, Raritan, Musconetcong, Rancocus, Salem, Shrewsbury, Tom's River, Great Eggharbor, Cohanzey, and Maurice River. None of these rivers are of any great length, though every part of the state abounds in rapid mill-streams. A connexion, by means of a canal, between the Hudson and Delaware basins was completed in 1831, at an expense of about 2,000,000 of dollars. The line leaves the Delaware at Phillipsburgh, opposite Easton in Pennsylvania, and is carried over Warren county, New Jersey, to its extreme north-east angle, about thirty miles; thence eastward through Morris and Essex counties, to the Passaic River, and along the valley of the latter to Newark. From that city it proceeds across Passaic and Hackinsack, and winds through the Bergen Marshes to Jersey city, opposite New York. Inclined planes are used on this canal instead of locks. During the year 1834 the Delaware and Raritan Rivers were connected by means of a canal from Brunswick to Bordentown, a distance of above thirty miles. This canal is calculated for sloop navigation; and has been constructed at an expense, with its feeder, of 2,500,000 dollars. The principal railroad is the Camden and Amboy, which unites the cities of New York and Philadelphia, crossing the state of New Jersey. It is sixty-one miles in length, and is connected with the Raritan and Delaware Canal. There is likewise a road from the manufacturing village of Patterson to New York, a distance of about sixteen miles; and another in progress (1835) from Jersey city, through Newark and Elizabethtown, to Brunswick.

New Jersey abounds in staples, composed of every product of its fields, woods, mines, fisheries, and manufactories. Some parts of the state are not well adapted to cultivation, being either sandy and barren, or rocky and mountainous; but large portions have a soil of great fertility, well suited to the cultivation of grain, and fitted for grazing; and accordingly vast numbers of cattle are raised for the markets of New York and Philadelphia. Large quantities of butter and cheese, of superior quality, are made; and apples, peaches, and fruits of all kinds, are raised in abundance. The manufactories of New Jersey are extensive and thriving. Iron is probably the most important. Bog ore is found in Burlington and Monmouth, and the mines of the northern counties are exceedingly rich. There are a number of forges and furnaces in active operation in several of the counties, and chain-cables are made at the town of Dover. The towns most engaged in manufactures are Newark and Patterson. The former is noted for the manufacture of leather, and the exercise of various occupations in which it is employed; also for the making of carriages, cabinet ware, and fancy chairs. Patterson is chiefly noted for its manufactures of cotton, hemp, and machinery. Glass of various kinds, and in large quantities, is made in different counties; and paper and gunpowder are manufactured to some extent. This state is rich in mineral productions. Besides the iron already mentioned, which is abundant, limestone prevails extensively. Marble and zinc are found, and ores of gold and silver have been discovered. Copper mines in Somerset and Bergen counties were wrought previously to the revolution, and extensive veins are believed to cross the state in a south-westerly direction, from Schuyler mine, near Belleville, to the river Delaware. Marl, well adapted for manuring the arenaceous districts, is found in their vicinage. Clay of superior quality for the arts is obtained in great abundance near South Amboy; and sand, adapted for the manufacture of the finest glass, is found in the county of Cumberland, from which it is conveyed to the principal manufactories of the union.

New Jersey is divided into fourteen counties, Bergen, Morris, Sussex, Warren, Essex, Somerset, Henderson, Middlesex, Burlington, Monmouth, Gloucester, Salem, Cumberland, and Cape May; and these are subdivided into townships. Trenton, the seat of government, is on the Delaware River, at the falls, on the great route between New York and Philadelphia, sixty miles south-west of the former, and thirty north-east of the latter. At the foot of the falls there is an elegant bridge over the Delaware, and that river is navigable for sloops and steam-boats to this place. The latter ply regularly between Trenton and Philadelphia. It is a handsome town, and contains a number of public buildings, amongst which the most conspicuous is the state-house. Trenton contains several respectable manufactories; and, in 1830, the population amounted to 3925. Newark is pleasantly situated on the western bank of the Passaic River, a few miles from its mouth. This is the handsomest town in the state, and contains several public buildings and religious edifices, together with extensive manufactories of different kinds. In this and the adjoining town of Orange there are valuable quarries of stone for building, and numerous tanneries. The population in 1830 amounted to 10,953. New Brunswick is situated on the western bank of the Raritan, thirty-three miles south-west of New York; and steam-boats regularly ply between the two cities. The buildings of New Brunswick, which has a city incorporation, are thinly distributed over a considerable extent of ground. Besides several public buildings and churches, there is a college and theological seminary. The former was established by the ministers of the Dutch reformed church, for the education of their clergy, and incorporated in 1770. The exercises, which were suspended for several years, were revived in 1825, under very favourable auspices. The theological seminary was established in the city in 1810, by the general synod of the Dutch reformed churches, and is to a certain extent connected with the college. In 1830, the population of New Brunswick amounted to 7831, half of whom are of Dutch extraction. Princeton is a pleasant village, eleven miles north-east of Trenton, and sixteen south-west of Brunswick. Here is the college of New Jersey, founded in 1738, and which has always been one of the most respectable and flourishing literary institutions in the country. The college edifice is designated Nassau Hall, and it contains a chapel, with sixty rooms for students. There are also buildings for the library, philosophical apparatus, museum, and other purposes. There are ten instructors, and above one hundred students. There is also a theological seminary at Princeton, connected with which are two professors, one of didactic and polemic theology, and another of ecclesiastical history. The edifice for the accommodation of the institution is an elegant stone building, containing rooms for one hundred students. Elizabethtown is pleasantly situated on Elizabethtown Creek, which empties itself into Staten Island Sound. Vessels of twenty or thirty tons come up to the town, and those of two or three hundred tons to within two miles of the town. A steam-boat plies between the city of New York and Elizabethtown Point. Patterson is situated on the Passaic, near the great falls, in a position much admired for the romantic scenery which surrounds it. It is the chief manufacturing town in the

Jerusalem. state, and in 1830 contained a population of 7731. The other towns are not of sufficient importance to demand individual description. They have all, according to their size, the usual number of public edifices and of religious houses.

Great attention to the cause of public education has recently been evinced throughout this state, and measures adopted which promise important results to the cause of universal enlightenment. Previously to the inquiry which was instituted in 1828, the system of instruction was very defective; but efforts have since been made to change this state of things. A school fund, exceeding 250,000 dollars, is managed by trustees under the authority of the legislature, and is steadily increasing; whilst a large portion of its annual income is distributed amongst the several townships, and is applied, augmented by moneys voluntarily raised by the townships, to the support of common schools, and otherwise to extend the means of education over the whole community. With regard to religion, almost every Christian denomination is represented in this state. The Presbyterians have eighty-five churches, eighty-eight ministers, twenty licentiates, and 12,519 communicants; the methodists 10,730 members; the Dutch reformed churches are twenty-eight in number, with as many ministers; the Baptists have thirty-four churches, twenty-one ministers, and 2324 communicants; the Episcopalians twenty ministers; the Friends are numerous; and there are some Congregationalists.

The legislature is composed of two bodies; the legislative council and the general assembly. The former is composed of fourteen members, one being returned from each county; and the latter of fifty members, the counties being represented by different numbers, from one to five. The governor is annually appointed, and, like most of the executive, judicial, and military officers, by the two houses in joint meeting. The judicial powers are, a court of chancery, modelled after that in England, the governor being chancellor; a supreme court of common law jurisdiction over the whole state, with a circuit court for the trial of issues of fact in civil cases in each county; courts of common pleas in the several counties, for the trial of civil causes; orphans' courts, for matters of testament, administration, and guardianship; and courts with presiding justices of peace, for the trial of small causes. The courts of criminal jurisdiction are, courts of general sessions of the peace, of oyer and terminer and general jail delivery, the supreme court, and the governor and council for the trial of impeachments exhibited by the house of assembly. According to the official documents of 1830, the military force of the state consists of 30,456 infantry, 1810 cavalry, 1886 artillery, 1115 riflemen, and 93 general, brigade, and staff officers, forming in all a body of 35,360 men.

The counties of Salem and Bergen in this state were respectively very early settled by the Swedes and Dutch, the latter people having emigrated from the neighbouring settlement of New York. By a charter dated in 1664, Charles II. granted this province to his brother James duke of York, who, having shortly afterwards granted it to subordinate agents, the English were not tardy in extending the settlement. In 1676, it was separated into two great divisions, East Jersey and West Jersey. Each owned a separate proprietor, who held both the rights of the soil and the powers of government; governors being appointed by them for the exercise of the latter, whilst the people were allowed to elect their own representatives. In 1702, the powers of government passed from the hands of the proprietors into those of Queen Anne, and the colony remained attached to the British crown until the declaration of American independence. During this period the governors were nominated by the crown, and the legislature, as before, chosen by the people, but afterwards representing the whole community, and sitting alternately at Burlington and Perth Amboy, then the principal towns of the respective divisions. From the earliest period of its history, New Jersey displayed much zeal and firmness in the cause of civil and religious liberty, and was amongst the earliest to resolve on independence. During the revolutionary conflict, it suffered much from having been the arena where the belligerent hosts frequently contended; and some of the most interesting scenes and the most arduous conflicts took place within its limits. This state has the two large and increasing cities of New York and Philadelphia on its borders; and, viewed in every light, although much smaller than many others in the union, it may be doubted whether it is not the most advantageously situated of any political subdivision in the republic. The population in 1820 was 277,575, and in 1830, 320,779; of these, 2446 were slaves. (R. R. R.)

JERUSALEM.

Jerusalem, one of the most ancient and renowned cities of which we have any account, formerly the capital of the Jewish empire, and now that of modern Palestine. It is situated on unequal ground, on a range of high hills, some few eminences of which overtop those on which the city stands, and the adjacent country is remarkably rocky and barren. The city, which is surrounded with a wall fifty feet in height, occupies an irregular square, facing the four cardinal points, and is about two and a half miles in circumference. The eastern wall, which is not quite so long as the other sides, runs straight along the brow of Mount Moriah, with the deep valley of Jehoshaphat below. The southern side is extremely irregular, taking a zigzag direction; the south-west extreme being terminated by a mosque built over the supposed sepulchre of David, on the summit of Mount Zion. The southern wall is quite straight and regular, and runs over slightly-declining ground. The side facing the west is the longest of the whole. The wall appears to be a modern work, all executed at the same time. It is flanked at irregular distances by square towers, and is guarded by battlements all around, with loop-holes for arrows or musketry. On the north the city is bounded by a level and apparently fertile space, covered with olive trees, particularly near the north-eastern angle. On the south is seen the steep acclivity of Mount Zion, and the Valley of Hinnom, on which are some cultivated spots and small garden enclosures. On the west the sterile summits of the hills scarcely rise above the dwellings; whilst eastward, the deep valley of Jehoshaphat, at the foot of the Mount of Olives, though partially relieved by spots with trees, presents, in general, a forbidding and barren appearance. The first aspect of Jerusalem has been variously described by different writers, and the city appears to be seen to more or less advantage according to the quarter from which it is approached. Dr Clarke was impressed with its grandeur when he first obtained a distant prospect of it. "Instead," he observes, "of a wretched and ruined town, by some described as the desolated remnant of Jerusalem, we beheld as it were a flourishing and stately metropolis, presenting a magnificent assemblage of domes, towers, palaces, churches, and monasteries, all of which, glittering in the sun's rays, shone with inconceivable splendour." "I can now account," says Chateaubriand, "for the surprise expressed by the crusaders and pilgrims at the first sight of Jerusalem, according to the reports of historians and travellers. I can affirm, that whoever has, like me, had the patience to read nearly two hundred modern accounts of the Holy Land, the rabbinical compilations, and the passages in the ancient writers, respecting Judæa, still knows nothing at all about it. I paused with my eyes fixed on Jerusalem, measuring the height of its walls, reviewing at once all the recollections of history from the patriarch Abraham to Godfrey of Bouillon, reflecting on the total change accomplished in the world by the mission of the Son of Man, and in vain seeking that temple, not one stone of which is left upon another. Were I to live a thousand years, never should I forget that desert, which yet seems to be pervaded by the greatness of Jehovah, and the terrors of death."[1] Dr Clarke, however, observes that there is another point from which Jerusalem is not seen to so much advantage; and accordingly Mr Browne, who approached it by the road from Jaffa, observes, that the first aspect of Jerusalem did not gratify his expectation; and Buckingham declares, that, independently of the feelings and recollections which the approach to this city cannot fail to awaken, its appearance disappointed his expectations, and "had certainly nothing of grandeur or beauty, of stateliness or magnificence, about it. It appeared like a walled town of the third or fourth class, having neither towers, nor domes, nor minarets within it; but strong, large, flat-roofed buildings, of the most unornamented kind, seated amid rugged hills, on a stony and forbidding soil, with scarcely a picturesque object in the whole compass of the surrounding view."[2] In like manner Sir Frederick Henniker asks, "Is this the city that men call the perfection of beauty and the joy of the whole earth? The town, which appears to me not worth possession, even without the trouble of conquest, is walled entirely round, is about a mile in length and half a mile in width, so that its circumference may be estimated at three miles. In three quarters of an hour I performed the circuit. It would be difficult to conceive how it could ever have been larger than it now is; for, independent of the ravines, the four outsides of the city are marked by the brook of Siloam, by a burial-place at either end, and by the hill of Calvary; and the hill of Calvary is now within the town, so that it was formerly smaller than it is at present. The best view of it is from the Mount of Olives; it commands the exact shape, and nearly every particular, namely, the church of the Holy Sepulchre, the Armenian convent, the mosque of Omar, St Stephen's Gate, the round topped houses, and the barren vacancies of the city. The mosque of Omar is the St Peter's of Turkey. The building itself has a light pagoda appearance; the garden in which it stands occupies a considerable part of the city, and, contrasted with the surrounding desert, is beautiful; but it is forbidden ground, and Jew or Christian entering within its precincts must, if discovered, forfeit either his religion or his life."[3] The diversity of opinion, nay, even the apparent contradiction, which prevails in the accounts of different travellers respecting Jerusalem, will be still further illustrated by M. de Lamartine's description of the exterior aspects of the holy city.

"This city," says he, "is not, as it has been represented, an unshapely and confused mass of ruins and ashes, over which a few Arab cottages are thrown, or a few Bedouin tents pitched; neither is it, like Athens, a chaos of dust and crumbling walls, where the traveller seeks in vain the shadow of edifices, the trace of streets, the phantom of a city; but it is a city shining in light and colour, presenting nobly to view her intact and battlemented walls, her blue mosque with its white colonnades, her thousand resplendent domes, from which the rays of the autumnal sun are reflected in a dazzling vapour; the façades of her houses, tinted by time and heat, of the yellow and golden hue of the edifices of Pæstum or of Rome; her old towers the guardians of her walls, to which neither one stone, one loop-hole, nor one battlement is wanting; and, above all, amidst that ocean of houses, that cloud of little domes which cover them, is a dark elliptical dome, larger than the others, overlooked by another and a white one. These are the churches of the Holy Sepulchre and of Calvary; from hence they are confounded, and appear drowned in the immense labyrinth of domes, edifices, and streets, which encompass them; and one finds it difficult to credit such a situation for Calvary and the Sepulchre, which, according to the ideas we derive from the gospel history, should be placed on a separate hill without the walls, and not in the centre of Jerusalem. The city, confined on the side of Mount Sion, has no doubt enlarged herself on the north, to embrace within her circuit those two sites which make her shame and glory, that of the murder of the just man, and the resurrection of the incarnate Deity.

"Such is the city from the height of the Mount of Olives. She has no horizon behind her to the west nor to the north. The line of her walls and her towers, the points of her numerous minarets, the arches of her shining domes, stand out in bold relief against the deep blue of an orient sky; and the town, thus exhibited on its broad and elevated platform, seems again to shine in all the antique splendour of its prophecies, or to be only waiting the word to rise in dazzling glory from its seventeen successive ruins, and to be transformed into that New Jerusalem which is to come out of the bosom of the desert radiant with brightness.

"The view is the most splendid that can be presented to the eye, of a city that is no more; for she still seems to exist as one full of life and youth: but on contemplating the scene with more attention, we feel that it is really no more than a fair vision of the city of David and Solomon. No noise arises from her squares and streets, no roads lead to her gates from the east or from the west, from the north or from the south, except a few paths winding among the rocks, on which you may meet only half-naked Arabs, some camel drivers from Damascus, or women from Bethlehem or Jericho, carrying on their heads a basket of raisins from Engaddi, or a cage of doves, to be sold on the morrow under the trebinthuses beyond the city gates. No one passed in or out; no mendicant even was seated against her curbstones; no sentinel showed himself at her threshold; we saw, indeed, no living object, heard no living sound; we found the same void, the same silence, at the entrance of a city containing 30,000 souls, during the twelve hours of the day, as we should have expected before the gates of Pompeii or Herculaneum.

"We saw nothing pass the gate of Damascus, except four funeral processions, silently winding their way along the walls to the Turkish cemetery; nor the gate of Sion, while we were within view, except a poor Christian, who had died in the morning of the plague, and was carried by four grave-diggers to the Grecian burial-place. They passed close by us, stretched the infectious corpse upon the ground, wrapped in its own garments, and in silence commenced digging its last bed under our horses' feet. The earth all around the city was freshly disturbed by similar sepultures, which the plague multiplied daily; and the only sensible noise outside the walls of Jerusalem was the monotonous plaints of the Turkish women bewailing their dead. I know not whether the plague was the only cause of the emptiness of the roads and the profound silence that reign-

Jerusalem. ed within and around Jerusalem, but I think not; for the Turks and Arabs turn not away from the inflictions of Omnipotence, which they are convinced may everywhere reach them, and that there is no road by which to escape; a sublime idea, but which often leads to the most fatal consequences.

"To the left of the platform, the temple, and the walls of Jerusalem, the hill which supports the city suddenly sinks, stretches itself, and descends in gentle slopes, sometimes broken by terraces of falling stones. On its summit, at some hundred paces from Jerusalem, stand a mosque, and a group of Turkish edifices, not unlike a European hamlet, crowned with its church and steeple. This is Sion, the palace, the tomb of David; the seat of his inspiration and of his joys, of his life and his repose. A spot doubly sacred to me, who have so often felt my heart touched and my thoughts rapt by the sweet singer of Israel,—the first poet of sentiment,—the king of lyrics. Never have human fibres vibrated to harmonies so deep, so penetrating, so solemn. Never has the imagination of poet been set so high, never has its expression been so true. Never has the soul of man expanded itself before man, and before God, in tones and sentiments so tender, so sympathetic, and so heartfelt. All the most secret murmurs of the human heart found their voice and their note on the lips and the harp of this minstrel. And if we revert to the remote period when such chaunts were first echoed on the earth; if we consider that at the same period the lyric poetry of the most cultivated nations sang only of wine, love, war, and the victories of the muses, or of the coursers at the Elcian games; we dwell with profound astonishment on the mystic accents of the prophet king, who addresses God the Creator as friend talks to friend; comprehends and adores His wonders, admires His judgments, implores His mercies, and seems to be an anticipatory echo of the evangelic poetry, repeating the mild accents of Christ before they had been heard. Prophet or not, as he is contemplated by the philosopher or the Christian, neither of them can deny the poet king an inspiration bestowed on no other man. Read Horace or Pindar after a psalm! For my part I cannot.

"I, the feeble poet of an age of silence and decay, had I domesticated at Jerusalem, should have selected for my residence and abiding place precisely the spot which David chose for his at Sion. Here is the most beautiful view in all Judæa, Palestine, or Galilee. To the left lies Jerusalem with its temple and its edifices, over which the eyes of the king or of the poet might rove at large without his being seen from thence. Before him, fertile gardens, descending in steep declivities, lead to the bed of that torrent, in the roar and foam of which he delights. Lower down, the valley opens and extends itself; fig-trees, pomegranates, and olives, overshadowing it. On one of these rocks, suspended over the rolling tide; in one of these sonorous grottoes, refreshed by the breeze and by the murmur of the waters; or at the foot of a trebinthus, ancestor of that which shelters me; the divine poet doubtless awaited those inspirations which he so melodiously poured forth. And why will they not here also visit me, that I might recount in song the griefs of my heart, and of the hearts of all men, in these days of perplexity, even as he sang of his hopes in an era of youth and of faith? Song, alas, no longer survives in the heart of man, for despair sings not. And until some new beam shall descend upon the obscurity of our times, terrestrial lyres will remain mute, and mankind will pass in silence from one abyss of doubt to another, having neither loved, nor prayed, nor sang.

"But to return to the palace of David. Here the eye rests upon the once verdant and watered valley of Jehoshaphat; a large opening in the eastern hills conducts it from steep to steep, from height to height, from undulation to undulation, even to the bason of the Dead Sea, which, in the far distance, reflects the evening sun-beams in its dull and heavy waters, giving, like the thick Venetian crystal, an unpolished and leaden tint to the light which gleams upon it. This sea is not, however, what the imagination may picture it, a petrified lake, amidst a dull and colourless horizon. It resembles one of the most beautiful lakes of Switzerland or Italy as it is seen from hence, reposing its tranquil waters beneath the shadow of the lofty mountains of Arabia (which stretch like the Alps as far as the eye can reach behind its waves), and amidst the projecting, pyramidical, conical, unequal, jagged, and sparkling ridges of the most distant mountains of Judæa. Such is the view from Sion. We will now proceed.

"There is another feature in the landscape of Jerusalem, which I could wish to have indelibly engraven on my memory, although I neither draw nor paint. It is the valley of Jehoshaphat. That valley, celebrated in the traditions of three religions, in which Jews, Christians, and Mahommedans unite to place the terrible arena of Supreme judgment. That valley which has already witnessed on its confines the grandest scene of the evangelical drama; the tears, the groans, and the death of Christ. That valley which all the prophets have successively visited, sending forth a cry of bitterness and horror, with which it seems still to vibrate. That valley through which shall one day pour the awful sound of a torrent of souls about to present themselves before their God for final judgment."[1]

What follows is part of an interior view of the holy city by the same gifted writer, and it appears to us to be instinct with devout feeling and high genius.

"Having walked down some other streets similar to those I have already described, we found ourselves in a little square, open at the north to a point of the heavens and to the Mount of Olives. A descent of a few steps to the left brought us to an open court, in which the *façade* of the church of the Holy Sepulchre was displayed. This church has been so often and so well described, that it is needless for me to enter upon the subject anew. It forms, especially in its exterior, a vast and beautiful monument of the Byzantine age; its architecture is severe, solemn, grand, and rich, for the period in which it was built; and it is a temple worthy of being erected, by the piety of man, over the tomb of the Son of Man. In comparing this church with others which the same epoch produced, it will be found superior to them all. St Sophia, much more colossal, is also much ruder in its structure; outwardly it is but a mountain of stone, flanked by little hills of stone. The Holy Sepulchre, on the contrary, presents an aerial and carved cupola; its scientific and graceful figure, with its doors, its windows, its capitals and cornices, displays, in addition to its massiveness, the incalculable cost of that ingenious fret-work, by which stone seems converted into lace, to render it worthy of a place in this monument erected to the grandest of human conceptions; and it bears impressed, no less on its details than on its aggregate effect, the idea to which it is dedicated. It is no longer, indeed, that church of the Holy Sepulchre constructed by Saint Helena, the mother of Constantine; the kings of Jerusalem successively retouched it, and embellished it with architectural ornaments in that half western, half Moorish style, of which the East furnished them both with the taste and with the models. But, such as it now stands, the exterior, in its Byzantine mass, its Greek, Gothic, and Arabesque decorations—even its fractures, the impress of time

[1] *Pilgrimage to the Holy Land*, vol. ii. p. 15-20, English translation, London, 1835.

 and barbarism upon its *façade*—offers no revolting contrast to the thoughts we bring to it, the thoughts it expresses. Its aspect excites no painful perception of a grand idea inadequately represented; of an exalting reminiscence profaned by the hand of man: on the contrary, the involuntary feeling inspired by it equals what I expected; man has done his best. The monument is not worthy of the tomb, but it is worthy of the human agents whose wish has been to do honour to this illustrious sepulchre; and we enter the vaulted and sombre vestibule of the nave under the influence of this first and serious impression.

"On the left of the entrance to the vestibule, which opens upon the same court as the nave, in a large deeply-hollowed niche, the Turks, the present guardians of the Holy Sepulchre, to whom belongs exclusively the privilege of opening or closing it, have established their divan, which is covered with rich Aleppo carpets; and there, when I passed, were squatted five or six venerable Turkish figures, with long white beards, their coffee-cups and pipes placed before them on the carpet. They saluted us with dignity and grace, and ordered one of the superintendents to accompany us to all parts of the church. I saw no trace in their countenances, their discourse, or their gestures, of the irreverence of which they are accused. They do not enter the church, but content themselves outside its doors, and address Christians with a seriousness and respect becoming the place and the object of visiting it. Possessors, by the vicissitude of war, of the sacred monument of the Christians, they do not destroy it and cast its ashes to the winds; they preserve it, they maintain around it an order, a police, a reverential silence, which the Christian communities, who contend for it, are far from observing themselves. They watch over the preservation of a relic common to all who bear the name of Christians, for the benefit of all, that every communion may enjoy in its turn the worship which all would gladly offer at the holy tomb. But for the Turks, that tomb, disputed by the Greeks, the Catholics, and the innumerable ramifications of the Christian world, would already have been a hundred times an object of strife between those rival and hostile communities; would have passed alternately into the exclusive possession of either party, and have been interdicted doubtless by each, during their hour of triumph, to all professors of the common faith who come not within their own pale. I see no justice in the calumnies heaped upon the Turks; the pretended brutal intolerance with which they are charged was manifested to my observation only in respect for what other men venerate and adore. Wherever a Mussulman sees the image of God in the opinions of his fellow-creatures, he bows down and he respects, persuaded that the intention sanctifies the form. They are the only tolerant people. Let Christians examine themselves, and ask in sincerity how they would have acted if the fortune of war had placed Mecca and Kaaba in their hands. Would the Turks then resort thither from all parts of Europe and of Asia, to revere, in peace, the carefully preserved monuments of Islamism?

"At the end of the vestibule we stood under the large cupola of the church, the centre of which, deemed by local tradition the centre of the earth, is occupied by a small monument enclosed within a larger, as a precious stone is enchased in other minerals. It is an oblong square, adorned with pilasters, a cornice, and a cupola, all of marble; the whole of a laboured and eccentric design, and executed in bad taste. It was rebuilt in 1817, by an European architect, at the expense of the Greek church, now in possession of it. All around this interior pavilion of the sepulchre extends the space of the external cupola, within which we walk freely, and find in the intervals between the piers chapels of great depth, each assigned to one of the mysteries of Christ's passion, and all containing some testimonies, real or supposed, of the scenes of the redemption. That part of the church which is not under the cupola is divided from it by a partition of painted wood, hung with pictures of the Greek school, and is exclusively reserved for the schismatic Greeks. In spite of the singular profusion of bad paintings and ornaments of every description, with which the walls and altars are overloaded, the general effect is solemn and religious, conveying the assurance that prayer under every form has taken possession of this sanctuary, and that pious zeal has accumulated within it every object which generations of superstitious but sincere worshippers have deemed precious in the sight of God. From hence a flight of steps, cut in the rock, conducts to the summit of Calvary, where the three crosses were posted; so that Calvary, the tomb, and several other sites of the drama of redemption, are united under the roof of a single edifice of moderate dimensions; a circumstance that appears but ill to accord with the gospel histories. We are not prepared by them to find the tomb of Joseph of Arimathea, which was cut in the rock, outside the walls of Sion, fifty paces from Calvary, the scene of executions, and enclosed within the circumference of the modern walls; but such is tradition, and it has prevailed. The mind cannot dispute over a scene like this the difference of a few paces between historical probability and tradition. Whether it were here or there, it is certain the events occurred at no great distance from the points marked out. After a few moments of deep and silent meditation devoted in each of these sacred spots to the remembrances awakened, we re-descended to the body of the church, and penetrated within the interior monument, which serves as a sort of stone curtain or envelope to the sepulchre itself. This is divided into two small sanctuaries; the first containing the stone on which the angels were seated when they answered the holy women, "*He is not here, he is risen;*" the second and last sanctuary enclosing the sepulchre itself, but covered with a sort of sarcophagus of white marble, which surrounds and entirely conceals from the eye the actual substance of the primitive rock in which the sepulchre was cut. This sacred chapel is lighted by lamps of gold and silver, perpetually maintained; and perfumed incense is burnt there night and day, warming and embalming the air. We suffered none of the temple officials to penetrate it with us, but entered one by one, separated by a curtain of crimson silk from the first sanctuary; we chose that no witness should disturb the solemnity of the place, and the privacy of the impressions each might experience according to his individual notions, and the measure and nature of his faith in the great event which the tomb commemorates. We staid each about a quarter of an hour, and none of us left it with dry eyes. Whatever form religious sentiments may have assumed in the soul of man; whether influenced by private meditation, by the study of history, by years, or the vicissitudes of the heart and mind; whether he have retained Christianity in its literal interpretation, and in the doctrines imbibed from his parents, or is only a philosophical and spiritual Christian; whether Christ be to him a crucified God, or no more than a holy man deified by virtue, inspired by supreme truth, and dying to bear testimony to his father; whether Jesus be in his eyes the Son of God or the Son of Man, divinity incarnate or humanity deified; Christianity is still the religion of his memory, of his heart, and of his imagination; and will not have so wholly evaporated before the winds of time and life as that the soul on which it was shed shall preserve no vestige of its primitive odour, or that its fading impressions can resist the revivifying and awfully affecting influence of its birth-place, and of the visible monuments of its earliest profession. To the Christian or to the philosopher, to the moralist or to the historian, this tomb is the boundary of two worlds, the ancient and the modern. From this point issued a truth that has renewed the universe; a civilization that has transformed all things; a word which has echoed over the whole globe. This tomb is the sepulchre of the old world, the cradle of the new; never was earthly stone the foundation of so vast an edifice; never was tomb so prolific; never did doctrine, inhumed for three days or three centuries, so victoriously rend the rock which man had sealed over it, and give the lie to death by so transcendent, so perpetual a resurrection.

"In my turn, and the last, I entered the Holy Sepulchre, my mind filled with these stupendous reflections, my heart touched by impressions yet more sacred, which remain a mystery between man and his soul, between the reasoning insect and his Creator. Such impressions admit not of words; they exhale with the smoke of the holy lamps, with the perfume of the censers, with the vague and confused murmur of sighs; they fall with those tears that spring to the eyes from remembrance of the first names we have lisped in infancy—of the father and the mother who inculcated them—of the brothers, the sisters, the friends with whom we have whispered them. All the pious emotions which have affected our souls in every period of life; all the prayers that have been breathed from our hearts and our lips in the name of him who taught us to pray to his Father and to ours; all the joys and griefs of which those prayers were the interpreters; are awakened in the depths of the soul, and produce, by their echoes, by their very confusion, a bewildering of the understanding, and a melting of the heart, which seek not language, but transpire in moistened eyes, a heaving breast, a prostrate forehead, and lips glued in silence to the sepulchral stone. Long did I remain in this posture, supplicating the Father of heaven, in that very spot from whence the most pathetic and comprehensive of prayers ascended for the first time to his throne; praying for my father here below, for my mother in another world, for all those who live or are no more, but our invisible link with whom is never dissolved: the communion of love always exists: the names of all the beings I have known and loved, or by whom I have been beloved, passed my lips on the stones of the Holy Sepulchre. I prayed last for myself, but ardently and devoutly. Before the tomb of him who brought the greatest portion of truth into the world, and died with the greatest self-devotion for that truth of which God has made him the word, I prayed for truth and courage. Never can I forget the words which I murmured in that hour, so critical to my moral life. Perhaps my prayer was heard; a bright ray of reason and conviction diffused itself through my understanding, giving me more clearly to distinguish light from darkness, error from truth. There are moments in the life of man, in which his thoughts, long fluctuating like the waves of a bottomless sea in vague uncertainty, touch at length upon a shore against which they break, and roll back upon themselves with new forms, and a current contrary to that which has hitherto impelled them. Was such a moment then mine? He who sounds all thoughts knows, and the time will perhaps come when I shall comprehend it. It was a mystery in my life which will hereafter be made plain."[1]

The ancient city of Jerusalem, with the splendid structures by which it was adorned during the brilliant period of the Jewish empire, has entirely disappeared in the course of successive conquests; and although many ancient monuments, the scenes of Scripture history, are shown to travellers, it is certain that no traces remain of Jerusalem excepting the surrounding scenery, those natural features which triumph alike over time and the rage of war. One of the most splendid edifices in the modern city is the mosque of Omar already alluded to, which is said to stand on the site of Solomon's temple. It was erected in the seventh century, by the caliph whose name it bears. It is an octagonal building, with numerous windows, surmounted by a dome in form resembling that of St Paul's in London, and about half the size. It is by far the most splendid and richest monument of architectural art in Jerusalem, or, according to Dr Clarke, in the Turkish empire, and, "considered externally," he adds, "far superior to the mosque of St Sophia in Constantinople. It has an imposing effect when seen from a distance, from the commanding situation which it occupies; and it relieves in a great degree the dull, monotonous aspect of the other streets and buildings."[2] It is crowned with a cupola, which is also octagonal, having a round window of coloured glass in each of its sides; and is surmounted by a dome, formerly of gilded copper, but now of lead.[3] "The lofty Saracenic pomp," says Dr Clarke, "so nobly displayed in the style of the building, its numerous arcades, its capacious dome, with all the stately decorations of the place; its extensive area paved and variegated with the choicest marbles, the extreme neatness observed in every avenue towards it; and, lastly, the sumptuous costume observable in the dresses of all the eastern devotees, passing to and from the sanctuary, make it altogether one of the finest sights the Mahommedans have to boast."[4] No access into the interior is allowed to Christians, under pain of death; and when Dr Clarke urged his attendant to permit his entrance, he replied that his life would be the price of his compliance. In earlier times, however, when Jerusalem was in possession of the Crusaders, the interior of the mosque was visited by Europeans, who have described its architecture and decorations. It is entered by four large gates, richly ornamented, facing the four cardinal points, with six columns of marble and porphyry. The interior is of white marble, and the pavement inlaid with marble of different colours. Thirty-two columns of gray marble, in two rows, support the arched roof and the dome; around these columns are chandeliers gilded or of bronze, on which are seven thousand lamps which burn from Thursday at sun-set to Friday at mid-day, and constantly during the feast of Ramadan. The church of the Holy Sepulchre is another of the remarkable monuments of Jerusalem. It is said to be the scene of the crucifixion, entombment, and resurrection of our Saviour, though no evidence appears to identify the spot. Buckingham, who visited it in 1816, mentions that it was burned down in the year 1806, and has since been rebuilt in a style of architecture and decoration greatly inferior to the original. The general plan of the whole building, however, says Buckingham, and the arrangement of the holy station which it contains, are so exactly preserved, that the descriptions of the earliest visitors apply as correctly to its present state as to its former. In its appearance it resembles, according to Dr Clarke, who saw the original edifice, an ordinary Roman Catholic church. It presents in form a singular mixture of eastern and western architecture; a combination which, though it offends against the critical rules of taste, produces, according to this traveller, an agreeable effect. It is 300 feet long and nearly 200 broad, and was built by Helena, the mother of Constantine. Over the door there was in the first edifice a bas-relief, representing the entrance of Christ into Jerusalem, and the multitude strewing palm branches in the way. On entering the church, Dr Clarke was shown a slab of white marble in the pavement, surrounded by a rail, which he was told was the spot where our Sa-

Jerusalem. viour's body had been anointed by Joseph of Arimathea. There is not the slightest proof of the identity of any of these holy places; but the authority of these legends is still kept up as a device for exacting money from the travellers and pilgrims who visit this celebrated city. The interior of this strange fabric is divided into two parts. The first is a kind of ante-chapel, on entering which, the visitors are shown, before the mouth of the sepulchre, a block of white marble, on which it is affirmed that the angel sat after the Saviour was laid in the tomb. The sepulchre itself is composed of thick slabs of that beautiful breccia commonly called verd-antique marble; and the entrance is rugged and broken, owing to so many fragments being carried off as relics. The interior of the original edifice was adorned with Corinthian columns of fine marble; but these being destroyed by the fire, the dome is now supported by tall and slender square pillars of masonry, plastered on the outside, and placed so thickly together as to produce the worst effect. The mean architecture of the central dome, and of the whole rotunda which surrounds the sepulchre itself, can only, says Buckingham, be exceeded by the wretched taste of its painted decorations. The attention of this last traveller was attracted by the capitals of two very large pillars, evidently very ancient. They were placed on two short, thick shafts, and serve to support the roof of a grotto in which the holy cross is said to have been found by St Helena. For every incident in the history of the Saviour's death and resurrection there is in this church a suitable locality. The place is pointed out where Christ was derided by the soldiers; where the soldiers divided his garments; where he was nailed to the cross, &c.; to all which miserable inventions implicit credit is attached by the credulous multitude who seek admission to the Holy Sepulchre. This place is the scene of the most impious extravagancies and absurdities, in which the Greek and Latin Christians equally participate during their festivals at Easter; and they frequently contend with each other, even to the shedding of their blood, for the privilege of first entering in to celebrate mass. In the galleries round the church are small buildings, containing apartments for the reception of friars and pilgrims; and almost every Christian nation maintained here a society of monks. But these, owing to the severe extortions of the Turks, have many of them deserted the holy city, though the Greeks and Latins, and also some Armenians, Copts, and Abyssinians still remain. Lamps are continually kept burning in the sepulchre. The last and most important monument which is shown is the tomb itself where Christ's body is said to have lain, another of those delusions which seem to form the staple manufacture of the holy city. Vast crowds nevertheless resort to visit the sepulchre; and Buckingham observes that his stay there was very short. "The crowds," he says, "pressing at the door; the smallness of the aperture at the entrance; the confined space within, hung round with crimson damask, and ornamented with silver lamps and painting; the hurry and bustle occasioned by the worshippers searching for their shoes left at the door, as every one went in barefooted; the struggles to be the first to get near enough to kiss the marble; and sometimes the forcibly putting off the turbans of those who might have forgotten to uncover their heads; presented altogether a scene of such confusion, that, added to the risk of suffocation in so impure an atmosphere, it drove us by rapidly to make room for others." The Holy Sepulchre, after having been for some time the most honoured sanctuary of the Christians, became a heathen altar, where pagan rites were celebrated. The Turks, who now possess it, suffer the tomb of the Messiah to remain unmolested, in consideration of the money paid to them by the Christian pilgrims for the privilege of visiting it. About forty paces from the sepulchre, beneath the roof of the same church, and on the same level, are shown two rooms, one above another. Close by the entrance into the lower chamber or chapel, were formerly the tombs of Godfrey of Bouillon, and of Baldwin, kings of Jerusalem. But these, we are informed by Buckingham, have been spitefully destroyed by the rival sect of the Greeks, so that not a vestige of them remains to mark even the spot on which they stood. At the extremity of the chapel is a fissure or cleft in the natural rock, said to have taken place in consequence of the earthquake that occurred at the crucifixion. This spot is narrated as Mount Calvary, the place of our Saviour's passion; and here, upon a contracted piece of masonry, are shown the marks of the three crosses on which Christ suffered, along with the two thieves. "After this," says Dr Clarke, "the traveller may be conducted through such a farrago of absurdities, that it is wonderful the learned men who have described Jerusalem should have filled their pages with any serious detail of them."

There is no evidence, however, to prove the identity of these holy places with the events of which they are supposed to have been the scene. It cannot, as is said, be Mount Calvary, for there is no mount; and in order to explain away this glaring inconsistency, it is affirmed that Mount Calvary was levelled to make way for the foundations of a church; that the sepulchre of Christ alone remained after the levelling had taken place, in the centre of the area; and that this was encased with marble; "not a syllable of which," says Dr Clarke, "is supported by any existing evidence offered in the contemplation of what is now called the tomb." Dr Clarke, denying that the places described to be Mount Calvary and the scene of the crucifixion had any claim to be so considered, was of opinion that he had discovered the real site where these great events took place. Having quitted the city of Jerusalem by the seven gates, and descended into a dingle or trench called Tophet or Gehinnom, he discovered, as he reached the bottom of the narrow dale, upon the sides of the opposite mountains, a number of excavations in the rock, which exhibited a series of subterranean chambers hewn with marvellous art, and containing repositories for the dead carved upon the sides of the solid rock. The doors were so low that it was necessary to stoop in order to procure an entrance, and to creep, in some instances, on the hands and knees; the doors were also grooved for the reception of immense stones, once squared and fitted for the grooves, by way of closing the entrances. These cemeteries are works of such labour and magnificence, that they might justly be considered as the sepulchres of kings. One, however, appears to have been constructed for a single individual; and from this circumstance, and from their being situated without the city, Dr Clarke concludes that here was the sepulchre of Joseph of Arimathea, and the place where our Lord was crucified; which was, according to the concurring testimony of all the evangelists, "the place of a skull," or a public cemetry, in the Hebrew, *Golgotha*. There are Greek inscriptions over the doors of these sepulchres, one of which is "of the Holy Sion." Continuing his researches further eastward along this dingle, and in the place called Aceldama, other ancient sepulchres were discovered by Dr Clarke, containing inscriptions and ancient paintings, executed after the manner of those found on the walls of Herculaneum and Pompeii; excepting that the figures represented were those of the apostles, the virgin, &c. with circular lines as symbols of glory encompassing their heads. These paintings were on the sides and on the roof of each sepulchral chamber; and although much injured by the Arabs or Turks, they still preserved a wonderful freshness of colour. These tombs are not nearly so ancient as those that were first noticed, being evidently constructed by Christians, after the dispersion, as Dr Clarke conjectures, of the Jews during the reign of Hadrian. At the foot of the Mount of Olives, on the east side of the brook Kedron, are the "sepulchre of the virgin," and those of the "patriarchs." The first is a cave hewn out with surprising skill and labour, in a rock of hard limestone, and is of great antiquity. The descent into this receptacle for the dead is by a flight of fifty marble steps, each of them twenty feet wide; within is a lofty and spacious vault, the largest of the *cryptæ* near Jerusalem, containing the tombs, real or imaginary, of the Virgin, of Joseph, of Anna, and of Caiaphas, with appropriate chapels to each. History throws no light upon the origin of this monument of human labour; and Dr Clarke, after the most careful examination, confesses himself unable to assign any probable era for its construction. The "sepulchres of the patriarchs" face that part of Jerusalem where the temple of Solomon was formerly erected. No representation has ever been given of these remarkable monuments that conveys an adequate idea of their grandeur. Their massive structure, the boldness of their design, and their sombre hue, as well as that of the surrounding rocks, impart to them a certain air of grandeur and sublimity, which is lost in the representation. In order to form two of these sepulchres, namely, those which are called the sepulchres of Absalom and Zechariah, the solid substance of the mountain has been cut away, and a sufficient area having in this manner been excavated, two monuments of prodigious size appear in the midst, cut out of an entire block of stone, and adorned with columns that appear to support the edifice. These columns are in the ancient style of the Doric order. The date of them has never yet been determined, nor by what people they have been erected. They are a continuation of one vast cemetery, extending along the base of all the mountainous elevations which surround Jerusalem on its southern and eastern sides; and whilst they are monuments of prodigious labour, such as were erected in those times by despotic kings, who could command labour to any extent, they also evince great progress in the arts, and, according to Dr Clarke, must have been the work of a powerful and flourishing people. There are other sepulchres to the north-west of Jerusalem, by the Damascus gate, which are minutely described by Maundrell.[1] An entrance cut out of the natural rock leads into an open court of about forty paces square; at the end of this court is a portico nine paces long and four broad, hewn out of the natural rock. An architrave running along its front, and sculptured with fruits and flowers in a light and airy style, is still discernible, though much defaced. At the end of the portico is the passage into the sepulchres, which consist of seven chambers cut out of the natural rock, and about seven or eight yards square, and exactly regular and just. In one of these was found the lid of a white marble coffin, exquisitely sculptured. It is mentioned by Maundrell, that he found one of the doors of the chambers of ash and of stone, and about six inches thick, still hanging; and it turned upon its hinges, which were also of stone. All knowledge of the origin of these singular structures is lost in remote antiquity, and the conjectures of travellers on the subject seem to be futile and vain.

Chateaubriand endeavours to prove that this was the tomb of Herod the tetrarch. Buckingham, however, considers his reasons as being far from conclusive; and, objecting also to the theories of Pococke and Clarke, he observes, "that, considering the changes of masters which Jerusalem has suffered, and the consequent variation in the taste of its possessors, it is at this moment a matter of extreme difficulty to separate the monuments of high antiquity from those of a more modern age, or to decide what parts of their remains preserve their original form, and what parts have been subsequently altered or ornamented by later hands." Such are the different impressions made by the same objects, that the last traveller, in reference to the observations of Dr Clarke, remarks, "that though this is the largest, the most extensive, and the most interesting of the monuments he had visited, there is not one which can be called either 'enormous' or 'splendid,' without the strangest abuse of terms." "The Jews," says M. de Lamartine, "had no architecture of their own; they borrowed from Egypt, from Greece, but more particularly, I think, from India. The key of every thing is in India; the generation of ideas and arts appears to me to go back there; they created Assyria, Chaldea, Mesopotamia, Syria; the great cities of the desert, as Balbec; then Egypt, then the islands of Crete and Cyprus; then Etruria, then Rome; then night came on, and Christianity, cradled at first by the Platonic philosophy, and afterwards by the barbarous ignorance of the middle ages, gave birth to our civilization and our modern arts."[2] Such is a specimen of the theories in which not only imaginative poets, but even sober, matter-of-fact travellers, are sometimes prone to indulge.

The ancient city of Jerusalem was so entirely destroyed that nothing remained by which the original plan could be traced, and hence the controversies still maintained among the learned respecting its localities. The more durable features of nature, however, still remain. From history we learn that the ancient city stood upon four eminences, with one very deep valley and two smaller ones dividing them. The most conspicuous of these eminences was that of Sion, called the Holy Hill, and the citadel of David to the south of the city. To the north of Sion was the hill of Acra; and on the east the third eminence, Mount Moriah, upon which was built the temple. It was bounded by the sepulchral caves on the north, by Mount Sion on the south, by the brook Kedron, which runs through the valley of Jehoshaphat, on the east, beyond which was the Mount of Olives, and by the hill of Acra on the west. There seems to be considerable uncertainty about the identity of these hills, though the Mount of Olives, covered with olive trees, still vindicates its origin; and the brook Kedron, receiving from its fountains, which yet abound in excellent water, the rivulet, or the dirty little brook, as Buckingham calls it, of Siloam, flows through the valley of Jehoshaphat; and the valley of Hinnom divides Mount Sion from Mount Moriah.

Jerusalem has long been celebrated as one of the holy places of the Christians, and has not only been the resort of numerous pilgrims, but the permanent residence of monks and Christians from various countries, such as the Latins, Greeks, Armenians, and Copts, who each of them have here a monastery and a church. The Latin convent of St Salvador is a large, irregular building, like a fortress, with courts and galleries within, and some small spaces of garden-land without, forming a safe retreat in time of intestine trouble. It is entered from a hilly street, by a large iron-cased door, beneath an overhanging building, which darkens the passage, and gives an air of gloom to the whole. Beyond this is a small open paved court below, with other still darker passages leading to the first flight of stairs. These being ascended, a range of galleries, winding in various directions, leads to the private apartments and domestic offices of the convent; and courts beyond, and terraces above, afford sufficient space for walks both morning and evening, with a commanding view of all Jerusalem and the surrounding country. In this edifice, Dr Clarke mentions that he was received by a body of the most corpulent friars he had ever beheld, who resembled the figures brought in

[1] *Journey from Aleppo to Jerusalem*, p. 76, 77

[2] *Pilgrimage to the Holy Land*, vol. ii. p. 80.

this country upon the stage by way of burlesquing the monkish character.

The friars are of the Franciscan order, who are under a vow of perpetual poverty, and live by alms. They are furnished with a bed and bedding, a table, wash-hand basin and jug, a lamp, a crucifix, and a chair, at the expense of the church, to which they may add other conveniences from their own funds. This convent of Jerusalem is called, by way of distinction, "Il Convento della Terra Santa," and is at the head of all the Catholic establishments throughout the Holy Land. It is recruited with monks from Naples, Sicily, and from the south of Spain, who, according to the account of Buckingham, are extremely discontented, and complain much of their banishment to this remote spot. The superior is immediately dependent on the pope; and the funds of the institution are supplied chiefly from Rome, aided by donations from other Catholic countries. The liberality of Ferdinand, king of Spain, was particularly extolled; and even the prince regent of England, afterwards George IV., had sent a gift of L.1500. The establishment of the convent consists of eighty-eight persons, who all mess together. The fast-days of the church are regularly observed; and the daily services of prayers and of masses, which are frequent and tedious. The morning hour of service is five; coffee is made at this hour, of which they all partake; they dine at ten, and sleep till past noon. There is no restriction at any time in the allowance of bread, wine, and vegetables, all of which are excellent. The monks are clothed once in two years, with an under garment, and outer cloak of dark-brown cloth, with the white knitted cord of St Francis, with which it is understood that they are to flagellate themselves for their sins. Strangers properly recommended, and especially if it is thought they can protect the convent, by their influence, from the exactions of the Turks, which are often heavy, are hospitably entertained in a room allotted for them. The monastery possesses considerable funds and stores. Dr Clarke was regaled with coffee, lemonade, and excellent tea, which was served profusely in bowls. The apartments are all paved with stone; and there are no less than twenty-two wells of excellent water within the walls. The discipline is strict, and implicit obedience is exacted by the superior, under pain of excommunication. All the inferior convents in Palestine and Syria are subject to this metropolitan convent: they are supplied from its funds when voluntary contributions fail; and all appointments are made by the superior. The church of the convent is not remarkable for size or beauty, though it is gaudily furnished with gilded candlesticks, censers, images, &c. and has a fine altar and an organ. The Greek monastery consists of many small establishments, which are said to be well supported. The church is partly subterranean, and is small and mean, the Greeks bestowing all their wealth on the decoration of the Holy Sepulchre. The Armenian convent is distinguished above all others for neatness and comfort, and for the cheerful aspect of the place. This edifice, with its church and gardens, occupies that point of the supposed Mount Zion that is within the city. The establishment is well provided with every comfort; its funds, contributed entirely by rich individuals, are superior to those of the other convents; and all Armenian worshippers and pilgrims are maintained here during their stay in the holy city. The church, which is supposed, according to the traditions current in Jerusalem, to be built on the spot where James the brother of John was killed with the sword, has a gorgeous and imposing appearance. Though small, it is lofty; the walls are everywhere covered with pictures, executed in the worst taste, yet, from their profusion and gay colouring, producing an agreeable effect. The pillars, as well as the portals of the door and the inner walls, are all cased with porcelain tiles, painted blue, with crosses and other devices; and the mosaic pavement is the most beautiful of its kind. The whole is carefully covered with rich Turkey carpets, excepting only a small space before the altar. To the left is a small recess, the pretended spot where St James was beheaded. It is ornamented with white marble sculpture, massy silver lamps, gilding and painting, which produces a surprising richness of effect. The door is even more beautiful, being composed entirely of tortoise-shell, mother-of-pearl, gold, and silver, all so exquisitely inlaid, that the skill of the workman seems to vie with the costliness and beauty of the materials. The altars, which front the door of the entrance, are all splendid; and the massy vessels, crosses, mitres, and candlesticks, of gold and silver, flowers, gems, and precious stones, have an appearance of splendour and richness which cannot be excelled. The Jews have a synagogue in a low and obscure street near the centre of the town, which is a large suit of subterranean rooms lighted by small windows. Here Mr Buckingham and Mr Bankes saw worship performed on the Jewish sabbath.

The population of Jerusalem is estimated, though not upon any accurate data, at between 20,000 and 30,000. The Mahommedans are the most numerous; and these consist of nearly equal portions of Osmanlee Turks from Asia Minor, descendants of pure Turks by blood, but Arabians by birth; a mixture of Turkish and Arab blood by intermarriages; and pure Syrian Arabs of an unmixed race. The few Europeans in Jerusalem consist only of the monks of the Catholic convent, and the still fewer Latin pilgrims who visit them. The Greeks are the most numerous. The Armenians are the next in order; and the inferior sects of Copts, Abyssinians, Syrians, Nestorians, Maronites, Chaldeans, &c. are scarcely perceptible in the crowd. The Jews amount to 1000 males and 3000 females; a great number of widows resorting to the holy city, where they are maintained by their own community. Their great happiness is to die at Jerusalem, and to be buried in the valley of Jehoshaphat. Though the Jews come from the most distant parts, they are easily distinguished by their dress and their physiognomy, which, says Buckingham, is "strikingly natural." The city is most populous from Christmas to Easter, and at the latter festival it is crowded, and exhibits a singular variety of costumes and languages. The only manufacture which flourishes at Jerusalem is that of crucifixes, chaplets, beads, crosses, shells, and relics, of which whole cargoes are shipped off for Italy, Portugal, and Spain. From the general sterility of the surrounding country, during the parching droughts of summer, every article of food is dear, and wages are high. The force usually maintained here consists of a thousand troops, Turks, Arabs, and Albanians.

Jerusalem is said to have been founded in the year of the world 2023, and at that time to have occupied only the two hills of Moriah and Acra. Fifty years after its foundation, it was taken by the Jebusites, descendants of Jebus, the son of Canaan, who built a fortress on Mount Zion, and gave to it the name of their father. Joshua made himself master of the lower town of Jerusalem, whilst the Jebusites remained masters of the citadel, from which they were dislodged by David, 824 years after the building of the city. David enlarged the citadel, and built a palace near it; and during the prosperous reign of Solomon the city was embellished by the celebrated temple. Palestine was afterwards invaded by the kings of Egypt, of Assyria, and, finally, by the king of Babylon; and by the latter, after having been previously plundered, it was utterly destroyed, and the Jews were carried away captive to Babylon. This happened in the year of the world 3513, about 600 years before the Christian era, 466½ years after the foundation of the temple by Solomon. After the conquest of Babylon by Cyrus, permission was given to the Jews to return to their own country. The work of rebuilding the city and temple of Jerusalem was begun, after seventy years of captivity, by Zerubbabel, and finished by Nehemiah. After the conquest of Persia by Alexander, and the division of his empire among his generals, the Jews endeavoured to regain their independence, which they with difficulty maintained against powerful neighbours. Jerusalem was taken by Ptolemy, and afterwards by Antiochus Epiphanes, who sacked the city, and placed an idol of Jupiter in the temple. The country was afterwards invaded by the kings of Asia, the successors of Alexander, who attempted to subjugate the country, and to impose on the Jews the idol worship of the Greeks. The patriotism and bravery of the Maccabees enabled the Jews successfully to resist these invaders. Jerusalem was at last subdued by the Romans, after which Jesus Christ appeared, and suffered in the city. The Jews rebelling against the tyranny of the Roman pro-consuls in the reign of Nero, the city was taken by Titus after a long siege, and given up to pillage, and the inhabitants were mostly taken and carried into slavery. A remnant was left till the reign of Adrian, who, incensed by repeated disturbances, razed the city completely to the ground, and on its ruins erected the Roman town of Ælia Capitolina. Jerusalem retained this name till the end of the seventh century, when Christianity, having been embraced by Constantine, became the established religion of the empire. The name of Jerusalem was then resumed, and the Empress Helena, the mother of Constantine, overthrew the idols that had been placed on the tomb of the Saviour, and caused to be erected the church which still remains, and which has been already described. Thirty years afterwards, in the year 363, the Emperor Julian, with a view of disproving the Christian prophecies, attempted to rebuild the temple, which attempt was, however, frustrated, according to the traditions of that age, by a miraculous interposition. During the progress and establishment of Christianity in the Roman empire, Jerusalem was enlarged and embellished, and became the resort of numerous pilgrims from all countries. About the year 636 the city was taken by the Caliph Omar, after a siege of four months, and was still a pious resort of numerous pilgrims, who were encouraged by the Turks to visit the Holy Sepulchre, as they derived a considerable profit from the tax which they imposed on them. Palestine was overrun by an inroad of the Turks in the year 1076, after which the defenceless pilgrims were exposed to continual outrage and violence from this barbarous people. The intelligence of their sufferings being carried to Europe, inflamed the zeal of the Christian world, and gave rise to those remarkable expeditions, the Crusades, for the deliverance of the Holy Land. Jerusalem was re-captured by the army under Godfrey of Bouillon, who was created king of Jerusalem, which city was held upwards of sixty years by five Latin kings, when it was again conquered by the Turks under Saladin, and was finally annexed to the Ottoman empire in 1517. Long. 35. 20. E. Lat. 31. 47. 47. N. (F.)

JESI, a city of Italy, in the province of Ancona, in the papal dominions. It is the see of a bishop, and contains a cathedral, five churches, seven monasteries, and five nunneries, and has 5000 inhabitants, whose chief occupation is making woollen and silk stockings. It is situated on the river Esino, about five miles from the Adriatic Sea, in a district rich in olives, wine, and mulberries.

JESSES, ribbons which hang down from garlands or crowns in falconry; also short straps of leather fastened to the hawk's legs, and so to vervels.

JESTING, or *concise wit*, as distinguished from continued wit or humour, lies either in the thought or the language, or both. In the first case it does not depend upon any particular words or turn of the expression. But the greatest fund of jests lies in the language, that is, in tropes or verbal figures; those afforded by tropes consist in the metaphorical sense of the words, and those of verbal figures principally turn upon a double sense of the same word, or a similitude of sound in different words. The third kind of jokes, which lie both in the sense and language, arise from figures of sentences, where the figure itself consists in the sense, but the wit turns upon the choice of the words.

JESUITS, or *the Society of Jesus*, a famous religious order of the Roman Catholic church, founded by Inigo de Loyola, called also Ignatius Loyola. The plan which this fanatic formed of its constitution and laws was suggested, as he gave out, and as his followers still teach, by the immediate inspiration of heaven. But, notwithstanding this high pretension, his design met at first with violent opposition. The pope, to whom Loyola had applied for the sanction of his authority to confirm the institution, referred his petition to a committee of cardinals; and as they represented the establishment as not only unnecessary, but dangerous, Paul refused to grant his approbation. At last, however, Loyola removed all his scruples by an offer which it was impossible for any pope to resist. He proposed, that besides the three vows of poverty, chastity, and monastic obedience, which are common to all the orders of regulars, the members of his society should take a fourth vow of obedience to the pope, binding themselves to go whithersoever he should command them for the service of religion, and without requiring any thing from the holy see for their support. At a time when the papal authority had received a severe shock by the revolt of so many nations from the Romish church; at a time when every part of the popish system was attacked with so much violence and success; the acquisition of a body of men thus peculiarly devoted to the see of Rome, and whom it might set in opposition to all its enemies, was an object of the highest consequence. Paul instantly perceiving this, confirmed the institution of the Jesuits by his bull, granted the most ample privileges to the members of the society, and appointed Loyola to be the first general of the order. The event fully justified Paul's discernment, in expecting such beneficial consequences to the see of Rome from this institution. In less than half a century, the society obtained establishments in every country that adhered to the Roman Catholic church; its power and wealth increased amazingly; the number of its members became great; their character as well as accomplishments were still greater; and the Jesuits were celebrated by the friends and dreaded by the enemies of the Catholic faith, as the most able and enterprising order in the church.

The constitution and laws of the society were perfected by Lainès and Aquaviva, the two generals who succeeded Loyola; men far superior to their master in abilities and in the science of government. They framed that system of profound and artful policy which distinguishes the order. The large infusion of fanaticism mingled with its regulations should be imputed to Loyola its founder. Many circumstances concurred in giving a peculiarity of character to the order of Jesuits, and in forming the members of it not only to take a greater share in the affairs of the world than any other body of monks, but also to acquire superior influence in the conduct of them.

The primary object of almost all the monastic orders is to separate men from the world, and from any concern in its affairs. In the solitude and silence of the cloister, the monk is called to work out his own salvation by extraordinary acts of mortification and piety. He is dead to the world, and ought not to mingle in its transactions. He can be of no benefit to mankind but by his example and by his prayers. The Jesuits, on the contrary, were taught to consider themselves as formed for action. They were chosen soldiers, bound to exert themselves continually in the service of God, and of the pope his vicar upon earth. Whatever tended to instruct the ignorant, whatever could be of use to reclaim or to oppose the enemies of the holy see, was their proper object. That they might have full leisure for this active service, they were totally exempted from those functions the performance of which forms the chief business of other monks. They appeared in no processions; they practised no rigorous austerities; they did not consume one half of their time in the repetition of tedious offices. But they were required to attend to all the transactions of the world, on account of the influence which these might have upon religion; they were directed to study the dispositions of persons in high rank, and to cultivate their friendship; and, by the very constitution as well as genius of the order, a spirit of action and intrigue was infused into all its members.

As the object of the society of Jesuits differed from that of the other monastic orders, the diversity was no less in the form of its government. The other orders might be considered as voluntary associations, in which whatever affected the whole body was regulated by the common suffrage of all its members. The executive power was vested in the persons placed at the head of each house or of the whole society; but the legislative authority resided in the community. Affairs of moment, relating to particular houses, were determined in conventual chapters; but such as respected the whole order were considered in general congregations. But Loyola, full of the ideas of implicit obedience, which he had derived from his military profession, provided that the government of his order should be purely monarchical. A general, chosen for life by deputies from the several provinces, possessed power which was supreme and independent, extending to every person and to every case. He, by his sole authority, nominated provincials, rectors, and every other officer employed in the government of the society, and he could remove them at pleasure. In him was vested the sovereign administration of the revenues and funds of the order. Every member belonging to it was at his disposal; and by his uncontrollable mandate he could impose upon them any task, or employ them in whatsoever service he pleased. To his commands they were required to yield not only outward obedience, but even to resign to him the inclinations of their own wills and the sentiments of their own understandings. They were to listen to his injunctions as if these had been uttered by Christ himself. Under his direction they were to be mere passive instruments, like clay in the hands of the potter, or like dead carcasses incapable of resistance. Such a singular form of policy could not fail to impress its character upon all the members of the order, and to give a peculiar force to all its operations. There is not in the annals of mankind any example of such a perfect despotism, exercised not over monks shut up in the cells of a monastery, but over men dispersed amongst all the nations of the earth.

As the constitutions of the order vested in the general absolute dominion over all its members, they carefully provided for his being perfectly informed with respect to the character and abilities of his subjects. Every novice who offered himself as a candidate for entering into the order was obliged to manifest his conscience to the superior, or a person appointed by him; and required to confess not only his sins and defects, but to discover the inclinations, the passions, and the bent of his soul. This manifestation they were required to renew every six months. The society, not satisfied with penetrating in this manner into the innermost recesses of the heart, directed each member to observe the words and actions of the novices. They were constituted spies upon their conduct, and were bound to disclose every thing of importance concerning them to the superior. In order that this scrutiny into their character might be as complete as possible, they served a long noviciate, during which they passed through the several gradations of ranks in the society; and they must have attained the full age of thirty-three years before they could be admitted to take the final vows, by which they became professed members. By these various methods, the superiors, under whose immediate inspection the novices were placed, acquired a thorough knowledge of their dispositions and talents. In order that the general, who was the soul which animated and moved the whole society, might have under his eye every thing necessary to inform or direct him, the provincials and heads of the several houses were obliged to transmit to him regular and frequent reports concerning the members under their inspection. In these they descended into minute details respecting the character of each person, his abilities natural or acquired, his temper, his experience in affairs, and the particular department for which he was best fitted. These reports, when digested and arranged, were entered into registers kept on purpose, that the general might at one comprehensive view survey the state of the society in every corner of the earth; observe the qualifications and talents of its members; and thus choose, with perfect information, the instruments which his absolute power could employ in any service for which he thought fit to destine them.

As it was the professed intention of the order of Jesuits to labour with unwearied zeal in promoting the salvation of men, this engaged them of course in many active functions. From their first institution, they considered the education of youth as their peculiar province; they aimed at being spiritual guides and confessors; they preached frequently in order to instruct the people; and they set out as missionaries to convert unbelieving nations. The novelty of the institution, as well as the singularity of its objects, procured the order many admirers and patrons. The governors of the society had the address to avail themselves of every circumstance in its favour; and in a short time the number as well as influence of its members increased prodigiously. Before the expiration of the sixteenth century, the Jesuits had obtained the chief direction of the education of youth in every catholic country of Europe. They had become the confessors of almost all its monarchs; an office of no small importance in any reign, but, under a weak prince, superior even to that of the minister himself. They were the spiritual guides of almost every person eminent for rank or power. They possessed the highest degree of confidence and interest with the papal court, as the most zealous and able champions of its authority. The advantages which an active and enterprising body of men might derive from all these circumstances are obvious. They formed the minds of men in their youth, and they retained an ascendant over them in their advanced years. They possessed, at different periods, the direction of the most considerable courts in Europe. They mingled in all affairs; they took part in every intrigue and revolution. The general, by means of the extensive intelligence which he received, could regulate the operations of the order with the most perfect discernment; and, by means of his absolute power, could carry them on with the utmost vigour and effect.

Along with the power of the order, its wealth continued to increase. Various expedients were devised for eluding the obligation of the vow of poverty. The order acquired ample possessions in every catholic country; and, by the number as well as magnificence of its public buildings, together with the value of its property, moveable or real, it vied with the most opulent of the monastic fraternities. Besides the sources of wealth common to all the regular clergy, the Jesuits possessed one which was peculiar to themselves. Under pretext of promoting the success of their missions, and of facilitating the support of their missionaries, they obtained a special license from the court of Rome to trade with the nations which they laboured to convert. In consequence of this, they engaged in an extensive and lucrative commerce both in the East and West Indies. They opened warehouses in different parts of Europe, in which they vended their commodities. Not satisfied with trade alone, they imitated the example of other commercial societies, and aimed at obtaining settlements. They accordingly acquired possession of a large and fertile province in the southern continent of America, and reigned as sovereigns over some hundred thousand subjects.

Unhappily for mankind, the vast influence which the order of Jesuits acquired by all these different means was often exerted with the most pernicious effect. Such was the tendency of that discipline observed by the society in forming its members, and such were the fundamental maxims in its constitution, that every Jesuit was taught to regard the interest of the order as the capital object to which every consideration was to be sacrificed. This spirit of attachment to their order, the most ardent perhaps that ever influenced any body of men, is the characteristic principle of the Jesuits, and serves as a key to the genius of their policy as well as the peculiarities in their sentiments and conduct.

As it was for the honour and advantage of the society, that its members should possess an ascendancy over persons in high rank or of great power, the desire of acquiring and preserving such a direction of their conduct with greater facility led the Jesuits to propagate a system of relaxed and pliant morality, which accommodates itself to the passions of men, justifies their vices, tolerates their imperfections, and authorizes almost every action that the most audacious or crafty politician would wish to perpetrate.

As the prosperity of the order was intimately connected with the preservation of the papal authority, the Jesuits, influenced by the same principle of attachment to the interests of their society, were the most zealous patrons of those doctrines which tend to exalt ecclesiastical power upon the ruins of civil government. They attributed to the court of Rome a jurisdiction as extensive and absolute as was claimed by the most presumptuous pontiffs in the dark ages. They contended for the entire independence of ecclesiastics on the civil magistrates. They published such tenets concerning the duty of opposing princes who were enemies of the catholic faith, as countenanced the most atrocious crimes, and tended to dissolve all the ties which connect subjects with their rulers.

As the order derived both reputation and authority from the zeal with which it stood forth in defence of the Romish church against the attacks of the Reformers, its members, proud of this distinction, considered it as their peculiar function to combat the opinions and to check the progress of the Protestants. They made use of every art, and employed every weapon against them. They set themselves in opposition to every gentle or tolerating measure in their favour; and they incessantly stirred up against them all the rage of ecclesiastical and civil persecution.

Monks of other denominations have indeed ventured to teach the same pernicious doctrines, and have held opinions equally inconsistent with the order and happiness of civil society. But, from reasons which are obvious, they either delivered such opinions with greater reserve, or propagated them with less success. Whoever recollects the events which have happened in Europe during two centuries, will find that the Jesuits may justly be considered as responsible for most of the pernicious effects arising from that corrupt and dangerous casuistry, from those extravagant tenets concerning ecclesiastical power, and from that intolerant spirit, which have been the disgrace of the church of Rome throughout that period, and which have brought so many calamities upon civil society.

But, amidst many bad consequences flowing from the institution of this order, mankind, it must be acknowledged, have derived from it some considerable advantages. As the Jesuits made the education of youth one of their capital objects, and as their first attempts to establish colleges for the reception of students were violently opposed by the universities in different countries, it became necessary for them, as the most effectual method of acquiring the public favour, to surpass their rivals in science and industry. This prompted them to cultivate with extraordinary ardour the study of ancient literature. It put them upon various methods for facilitating the instruction of youth; and, by the improvements which they made in education, they contributed so much towards the progress of polite learning, that upon this account they have merited well of society. Nor has the order of Jesuits been successful only in teaching the elements of literature; it has likewise produced eminent masters in many branches in science, and can alone boast of a greater number of ingenious authors than all the other religious fraternities taken together.

But it is in the new world that the Jesuits exhibited the most wonderful display of their abilities, and contributed most effectually to the benefit of the human species. The conquerors of that unfortunate portion of the globe had nothing in view but to plunder, to enslave, and to exterminate its inhabitants. The Jesuits alone made humanity the object of their settling there. About the beginning of the seventeenth century, they obtained admission into the fertile province of Paraguay, which stretches across the southern continent of America, from the bottom of the mountains of Potosi to the confines of the Spanish and Portuguese settlements on the banks of the river La Plata. They found the inhabitants in a state very little different from that which takes place amongst men when they first begin to unite together; strangers to the arts, subsisting precariously by hunting or fishing, and hardly acquainted with the first principles of subordination and government. The Jesuits set themselves to instruct and to civilize these savages. They taught them to cultivate the ground, to rear tame animals, and to build houses. They brought them to live together in villages. They trained them to arts and manufactures. They made them taste the sweets of society, and accustomed them to the blessings of security and order. These people became the subjects of their benefactors, who governed them with a tender attention, resembling that with which a father directs his children. Respected and beloved almost to adoration, a few Jesuits presided over some hundred thousand Indians. They maintained a perfect equality amongst all the members of the community. Each of them was obliged to labour, not for himself alone, but for the public. The produce of their fields, together with the fruits of their industry of every species, were deposited in common storehouses, from which each individual received every thing necessary for the supply of his wants. By this institution, almost all the passions which disturb the peace of society, and render the members of it unhappy, were extinguished. A few magistrates, chosen for the most part by the Indians themselves, watched over the public tranquillity, and secured obedience to the laws. The sanguinary punishments frequent under other governments were unknown. An admonition from a Jesuit, a slight mark of infamy, or, upon some singular occasion, a few lashes with a whip, were sufficient to maintain good order amongst these innocent and happy people.

But even in this meritorious effort of the Jesuits for the good of mankind, the genius and spirit of their order mingled and were discernible. They plainly aimed at establishing in Paraguay an independent empire, subject to the society alone, and which, by the superior excellence of its constitution and police, could scarcely have failed to extend its dominion over all the southern continent of America. With this view, in order to prevent the Spaniards or Portuguese in the adjacent settlements, from acquiring any dangerous influence over the people within the limits of the province subject to the society, the Jesuits endeavoured to inspire the Indians with hatred and contempt of these nations. They cut off all intercourse between their subjects and the Spanish or Portuguese settlements. They prohibited any private trader of either nation from entering their territories. When they were obliged to admit any person in a public character from the neighbouring governments, they did not permit him to have any conversation with their subjects; and no Indian was allowed even to enter the house where these strangers resided, unless in the presence of a Jesuit. In order to render any communication between them as difficult as possible, they industriously avoided giving the Indians any knowledge of the Spanish or of any other European language; but encouraged the different tribes which they had civilized to acquire a certain dialect of the Indian tongue, and laboured to make that the universal language throughout their dominions. As all these precautions, without military force, would have been insufficient to render their empire secure and permanent, they instructed their subjects in the European arts of war. They formed them into bodies of cavalry and infantry, completely armed and regularly disciplined. They provided a great train of artillery, as well as magazines stored with all the implements of war. Thus they established an army so numerous and well appointed, as to be formidable in a country where a few sickly and ill-disciplined battalions composed all the military force kept on foot by the Spaniards or Portuguese.

Such were the laws, the policy, and the genius of this formidable order, of which, however, a perfect knowledge has only been of late attainable. Europe had observed, for two centuries, the ambition and power of the order. But whilst it felt many fatal effects of these, it could not fully discern the causes to which they were to be imputed. It was unacquainted with many of the singular regulations in the political constitution or government of the Jesuits, which formed the enterprising spirit of intrigue that distinguished its members, and elevated the body itself to such a height of power. It was a fundamental maxim with the Jesuits, from their first institution, not to publish the rules of their order. These they kept concealed as an impenetrable mystery. They never communicated them to strangers, nor even to the greater part of their own members. They refused to produce them when required by courts of justice; and, by a strange solecism in policy, the civil power in different countries authorized or connived at the establishment of an order of men, whose constitution and laws were concealed with a solicitude which alone was a good reason for excluding them. During the prosecutions carried on against them in Portugal and France, the Jesuits were so inconsiderate as to produce the mysterious volumes of their institute. By the aid of these authentic records, the principles of their government may be delineated, and the sources of their power investigated, with a degree of certainty and precision which, previously to that event, it was impossible to attain. The pernicious effects, however, of the spirit and constitution of this order rendered it early obnoxious to some of the principal powers in Europe, and gradually brought on its downfall. The Emperor Charles V. saw it expedient to check its progress in his dominions; it was expelled from England by a proclamation of James I. in 1604, from Venice in 1606, from Portugal in 1759, from France in 1764, from Spain and Sicily in 1767, and it was totally suppressed and abolished by Pope Clement XIV. in 1773. In 1801, Pius VII. re-established the society of Jesuits, but only for Russia; and in 1814, the same pope re-established it throughout the whole earth. The following judicious and discriminating character of the order is from the masterly pen of Sir James Mackintosh, and forms the conclusion of the eighth chapter of his Historical View of the Reign of James II.

" The party which had now the undisputed ascendant was denominated Jesuits, as a term of reproach, by the enemies of that famous society in the church of Rome, as well as among the Protestant communions. A short account of their origin and character may facilitate a faint conception of the admiration, jealousy, fear, and hatred, the profound submission or fierce resistance, which that formidable name once inspired. Their institution originated in pure zeal for religion, glowing in the breast of Loyola, a Spanish soldier; a man full of imagination and sensibility, in a country where wars, rather civil than foreign, waged against unbelievers for ages, had rendered a passion for spreading the catholic faith a national point of honour, and blended it with the pursuit of glory as well as with the memory of past renown. The legislative forethought of his successors gave form and order to the product of enthusiasm, and bestowed laws and institutions on their society which were admirably fitted to its various ends. Having arisen in the age of the reformation, they naturally became the champions of the church against her new enemies. Being established in the period of the revival of letters, instead of following the example of the unlettered monks, who decried knowledge as the mother of heresy, they joined in the general movement of mankind; they cultivated polite literature with splendid success; they were the earliest, and, perhaps, the most extensive reformers of European education, which, in their schools, made a larger stride than it has at any succeeding moment; and, by the just reputation of their learning, as well as by the weapons with which it armed them, they were enabled to carry on a vigorous contest against the most learned impugners of the authority of the church. Peculiarly subjected to the see of Rome by their constitution, they became ardently devoted to its highest pretensions, in order to maintain a monarchical power, of which they felt the necessity for concert, discipline, and energy in their theological warfare.

" While the nations of the Spanish peninsula hastened with barbaric chivalry to spread religion by the sword in the newly explored regions of the East and the West, the Jesuits alone, the great missionaries of that age, either repaired or atoned for the evils caused by the misguided zeal of their countrymen. In India they suffered martyrdom with heroic constancy. They penetrated through the barrier which Chinese policy opposed to the entrance of strangers; they cultivated the most difficult of languages with such success as to compose hundreds of volumes in it; and, by the public utility of their scientific acquirements, they obtained toleration, patronage, and personal honours, from that jealous government: and the natives of America, who generally felt the superiority of the European race only in a more rapid or a more gradual destruction, and to whom even the excellent Quakers dealt out little more than penurious justice, were, under the paternal rule of the Jesuits, reclaimed from savage manners, and instructed in the arts and duties of civil life. At the opposite point of society they were fitted, by their release from conventual life, and their allowed intercourse with the world, for the perilous office of secretly guiding the conscience of princes. They maintain the highest station as a religious body in the literature of catholic countries. No other association ever sent forth so many disciples who reached such eminence in departments so various and unlike. While some of their number ruled the royal penitents at Versailles or the Escurial, others were teaching the use of the spade and the shuttle to the naked savages of Paraguay; a third body daily endangered their lives in an attempt to convert the Hindus to Christianity; a fourth carried on the controversy against the reformers; a portion were at liberty to cultivate polite literature, and the greater part continued to be employed either in carrying on the education of catholic Europe, of which they were the first improvers, or in the government of their society, in ascertaining the ability and disposition of the junior members, so that well-qualified men might be selected for the extraordinary variety of offices in their immense commonwealth. The most famous constitutionalists, the most skilful casuists, the ablest schoolmasters, the most celebrated professors, the best teachers of the humblest mechanical arts, the missionaries who could most bravely encounter martyrdom, or who with most patient skill could infuse the rudiments of religion into the minds of ignorant tribes or prejudiced nations, were the growth of their fertile schools. The prosperous administration of such a society for two centuries is probably the strongest proof afforded from authentic history that an artificially formed system of government and education is capable, under some circumstances, of accomplishing greater things than the general experience of it would warrant us in expecting from it. Even here, however, the materials were supplied and the first impulse given by enthusiasm; and in this memorable instance the defects of such a system are discoverable. The whole ability of the members being constantly, exclusively, and intensely directed to the various purposes of the order, the mind of the Jesuits had not the leisure or liberty necessary for works of genius, or even for discoveries in science, to say nothing of original speculations in philosophy, which are interdicted by implicit faith. That great society, which covered the world for two hundred years, has no names which can be opposed to those of Pascal and Racine, produced by the single community of Port Royal, which was in a state of persecution during the greater part of its short existence. But this remarkable peculiarity amounts perhaps to little more than that they were more eminent in active than in contemplative life. A far more serious objection is the manifest tendency of such a system, while it produces the precise excellences aimed at by its mode of cultivation, to raise up all the neighbouring evils with a certainty and abundance, a size and malignity, unknown to the freer growth of nature. The mind is narrowed by the constant concentration of the understanding; those who are habitually intent on one object, learn at last to pursue it at the expense of others equally or more important. The Jesuits, the reformers of education, sought to engross it, as well as to stop it at their own point. Placed in the front of the battle against the Protestants, they caught a more than ordinary portion of that theological hatred against their opponents which so naturally springs up where the greatness of the community, the fame of the controversialist, and the salvation of mankind, seem to be at stake. Affecting more independence in their missions than other religious orders, they were the formidable enemies of episcopal jurisdiction; and thus armed against themselves the secular clergy, especially in Great Britain, where they were the chief missionaries. Intrusted with the irresponsible guidance of kings, they were too often betrayed into a compliant morality; excused probably to themselves by the great public benefits which they might thus obtain by the numerous temptations which seemed to palliate royal vices, and by the real difficulties of determining, in many instances, whether there was more danger of deterring such persons from virtue by unreasonable austerity, or of alluring them into vice by unbecoming relaxation. This difficulty is indeed so great, that casuistry has, in general, vibrated between these extremes, rather than rested near the centre. To exalt the papal power, they revived the scholastic doctrine of the popular origin of government, that rulers might be subject to the people, while the people themselves, on all questions so difficult as those which relate to the limits of obedience, were to listen with reverential submission to the judgment of the sovereign pontiff, the common pastor of sovereigns and subjects, the unerring oracle of humble Christians in all cases of perplexed conscience. The ancient practice of excommunication, which, in its original principle, was no more than the expulsion from a community of an individual who did not observe its rules, being stretched so far as to interdict intercourse with offenders, and, by consequence, to suspend duty towards them, became, in the middle age, the means of absolving nations from obedience to excommunicated sovereigns. Under these specious colours both popes and councils had been guilty of alarming encroachments on the civil authority. The church had indeed never solemnly adopted the principle of these usurpations into her rule of faith or of life, though many famous doctors gave them a dangerous continuance. She had not condemned, or even disavowed, those equally celebrated divines who resisted them; and though the court of Rome undoubtedly patronized opinions so favourable to its power, the catholic church, which had never pronounced a collective judgment on them, was still at liberty to disclaim them, without abandoning her haughty claim of exemption from fundamental error. On the Jesuits, as the most staunch of the polemics who struggled to exalt the church above the state, and who ascribed to the supreme pontiff an absolute power over the church, the odium of these doctrines principally fell. Among reformed nations, and especially in Great Britain, the greatest of them, the whole order was regarded as incendiaries, perpetually plotting the overthrow of protestant governments, and as immoral sophists, who employed their subtle casuistry to silence the remains of conscience in tyrants of their own persuasion. Nor was the detestation of Protestants rewarded by general popularity in catholic countries. All other regulars envied their greatness; the universities dreaded their acquiring a monopoly of education. Monarchs, the most zealously catholic, though they often favoured individual Jesuits, often also looked with fear and hatred on a society who would reduce them to the condition of vassals of the priesthood; and in France, the magistrates, who preserved their integrity and dignity in the midst of general servility, maintained a more constant conflict with these formidable adversaries of the independence of the state and the church. The kings of Spain and Portugal envied their well-earned authority, in the missions of Paraguay and California, over districts which they had conquered from the wilderness. The impenetrable mystery in which a part of their constitution was enveloped, though it strengthened their association, and secured the obedience of its members, was an irresistible temptation to abuse power, and justified the apprehensions of temporal sovereigns, while it opened an unbounded scope for heinous accusations. Even in the eighteenth century, when many of their peculiarities had become faint, and they were perhaps little more than the most accomplished, opulent, and powerful of religious orders, they were charged with spreading secret confraternities over France. Their greatness became early so invidious as to be an obstacle to the advancement of their members; and it was generally believed that if Bellarmine had belonged to any other than the most powerful order in Christendom, he would have been raised to the chair of Peter. The court of Rome itself, for whom they had sacrificed all, dreaded auxiliaries who were so potent that they might easily become masters. These champions of the papal monarchy were regarded with jealousy by popes whose policy they aspired to dictate or control. Temporary circumstances at this time created a more than ordinary alienation between the Jesuits and the Roman court. They, in their original character of a force raised for the defence of the church against the Lutherans, always devoted themselves to the temporal sovereign who was at the head of the catholic party; they were attached to Philip II. at the time when Sextus V. dreaded his success; and they now placed their hopes on Louis XIV., in spite of his patronage, for a time, of the independent maxims of the Gallican church. On the other hand, Odeschalchi, who governed the church under the name of Innocent XI., feared the growing power of France, resented the independence of the Gallican church, and was, to the last degree, exasperated by the insults offered to him in his capital by the command of Louis. He was born in the Spanish province of Lombardy, and, as an Italian sovereign, he could not be indifferent to the bombardment of Genoa, and to the humiliation of that respectable republic, by requiring a public submission from the doge at Versailles. As soon, then, as James became the pensioner and creature of Louis, the resentments of Odeschalchi prevailed over his zeal for the extension of the church.

"The Jesuits had treated himself, and those of his predecessors who hesitated between them and their opponents, with offensive liberty. While they bore sway at Versailles and St James's, they were on that account less obnoxious to the Roman court. Men of wit remarked at Paris, that things would never go well till the pope became a Catholic, and King James a Huguenot. Such were the intricate and dark combinations of opinions, passions, and interests, which placed the nuncio in opposition to the most potent order of the church, and completed the alienation of the British nation from James, by bringing on the party which now ruled his councils the odious and terrible name of Jesuits."

J E S U S.

JESUS, the Divine Author of the Christian religion, was born at Bethlehem, a city of the tribe of Judah, about six miles south-east from Jerusalem. His mother was a Jewish virgin named Mary, the betrothed wife of Joseph, both in the humblest rank of life, though both of the royal race of David. The date of his birth is not mentioned in the sacred record; and there has been a difference of opinion among the learned who have engaged in the inquiry, respecting the precise period when it took place. It is now, however, generally agreed upon, that it must be fixed a few years earlier than is indicated by the epoch of our era, which, according to the common computation, corresponds with A. U. 754. We know that Jesus was born before the death of Herod the Great;[1] and it appears from Josephus,[2] that Herod died before the Jewish passover A. U. 750. From calculations founded on other parts of the gospel history, and particularly on a comparison between Luke, iii. 1 and 23, many have supposed that the nativity was in A. U. 747; and in this opinion some have been confirmed by the conjecture of Kepler, that the conjunction between Jupiter and Saturn, which took place in that year, was the star seen by the wise men; though it may be justly questioned how far the principles of scriptural interpretation admit of the supposition that the phenomenon referred to corresponds with the particulars mentioned by St Matthew.[3] In regard to the day or month in which the Saviour was born, a subject to which the devotion of a large proportion of the Christian world has attached much importance, we have no means of accurate knowledge. The description given[4] of shepherds watching their flocks by night, is inconsistent with the idea that it could have been in December or January, or during the heat of the summer months; as we know that in these periods the herds were no longer left in the fields.[5] At other times of the year the flocks might be turned out to pasture day and night in the south of Palestine; but there is no circumstance referred to by any of the evangelists to determine whether it was in spring or in autumn that Jesus was born.[6]

The chronological error in the vulgar era, and in the season for celebrating the festival of Christmas, does not in any way affect the truth of the gospel history; and cannot indeed appear strange, when it is considered that several centuries elapsed before the method of computing time by the birth of Christ was introduced, and that the festival of the nativity was not observed in the primitive church. During the first three centuries, the Christians adopted the ordinary modes of reckoning time, which prevailed among the heathen around them. Different methods were afterwards employed; and it was not till the sixth century that a Roman abbot named Dionysius the Less was induced, by motives of religion, to have recourse to the expedient of determining dates by the number of years from the period when the Son of God was born of a woman. The commemoration of the day of the nativity was not generally observed throughout the Christian world till the fourth century. At that time the western church fixed upon the 25th of December, and their example was generally followed.[7] Different causes have been assigned for the choice of this day. Sir Isaac Newton, in his work on Daniel, supposes that it was agreeably to the principle by which the chief feasts were fixed at the cardinal points, without regard to historical accuracy; as the annunciation at the vernal equinox, and St John the Baptist's day at the summer solstice. Hospinian and others have been of opinion that the festivities connected with the celebration of Christmas were intended to make up for the Saturnalia, conformably to the practice which had been acted upon from an earlier period, of smoothing the way for the conversion of the heathen, by

[4] Luke, ii. 8.

[5] "Pluvia prima descendit, die 17, M. Marchevan (Novem.), tunc armenta redibant domum nec pastores in tuguriis amplius habitabant in agris," &c. (*Gemar. Nedar.* 63.) Again, we read in Jerome, that in summer, "juxta ritum Palestinæ et multarum orientis provinciarum quæ ob pratorum et fœni penuriam paleas præparant usui animantium." (*Comm. Is.* lib. viii.)

[6] Various attempts have been made to connect the birth of Jesus with the feast of the Passover and the feast of Tabernacles; but the conclusions have been generally drawn from vague and fanciful analogies, and do not rest on historical grounds. See Hales' *Chronology*, vol. i.; and Greswell's *Dissertations on the Harmony of the Gospels*, diss. x.

[7] Clemens Alexandrinus mentions (Strom. i.), that some celebrated the natvity on the 20th of May, others on the 20th of April. The 6th of January was celebrated by the Basilidian Gnostics as the day of the nativity and of the baptism. This custom afterwards became general for a time throughout the East. And when the birth-day was fixed by the western church on the 25th of December, the 6th of January continued to be observed as the Epiphany.

presenting their idolatrous ceremonies under a new form. And there is not wanting reason to suppose, that from the winter solstice being observed as the birth-day of the sun, when that luminary, returning from the south, seemed to be restored to the world, the transition was suggested to the celebration of the birth of him who was the life and light of the world.[1]

The circumstances connected with the birth of Jesus corresponded in a remarkable degree with the predictions of the Jewish prophets respecting the Messias. He belonged to the tribe of Judah, and was of the house of David. Events, over which his earthly kindred had no control, fixed his birth at Bethlehem, from which place the promised Deliverer was to spring. The seventy prophetic weeks of Daniel were approaching to their termination. And so determinate were these and other predictions, that a general opinion prevailed, even in heathen countries, that the tide of time was bringing our race to a mighty epoch, and that a prince was to arise in the East who was to obtain the empire of the world.[2] The wisdom of Divine Providence was also shown in the appointed scene and season of the birth of Jesus. From the geographical situation of Palestine, forming a part of Asia, touching upon Africa, and connected by the Mediterranean with the whole of Europe, the Jews enjoyed the best opportunities of diffusing the knowledge of their principles. And the intercourse between remote nations, occasioned by the conquests of Alexander and the progress of the Roman arms, afforded increased facilities for propagating new opinions, while it forced upon men's notice the different forms of national worship, and led to an examination of the great principles of religious belief.

Soon after the birth of Jesus, his parents fled with him to Egypt, to save him from the fury of Herod, whose suspicions were awakened by the idea of a rival to his throne.[3] An uncertain tradition fixes the spot of the residence of the holy family at Matarea, near the ancient Heliopolis; and one of the apocryphal gospels contains various idle accounts of miracles which marked the presence of a superior being. From such traditions the Jews took occasion to circulate many ridiculous tales of magical arts learned by Jesus while in Egypt, which were frequently referred to by some of the early philosophic opponents of the Christian faith. The malignant insinuations of Celsus, however, and the absurd legends which long found currency among the Jews, are wholly inconsistent with the authentic narrative of the return from Egypt upon the death of Herod, when Jesus might still be said to be in infancy.

Upon their arrival in Palestine, Joseph was led to take up his residence in Nazareth, in Galilee. Here the opening character of Jesus engaged the love and excited the admiration of all who knew him.[4] And, even before his childhood was ended, in his twelfth year, when his parents carried him up to one of the annual Jewish feasts, we find him attracting the notice of the learned Rabbis, entering into discussion with them, and filling them with astonishment at his extraordinary knowledge and sagacity. It would appear that, according to the custom of his countrymen, he followed the trade of his foster-father. In Mark, vi. 3, he is spoken of familiarly as "the carpenter."[5] And Justin Martyr tells us, that while he sojourned on earth, he was employed in the ordinary occupations of a carpenter.[6]

In this lowly situation, and in the midst of these servile employments, a character was silently maturing, such as the world had never before witnessed; and those lofty designs were conceived, the accomplishment of which was to give a new impress to the condition of society, and to alter the destiny of our race. Frequent attempts have been made to explain by the operation of natural causes, how, in circumstances so unfavourable, a character like that of our Saviour's could have arisen; and various theories have been framed respecting the manner in which the plan to which he devoted himself was suggested to his mind. The insufficiency of these attempts we shall afterwards consider. In the mean time, however, it may be remarked, that, though no explanation can be given, from circumstances merely external, of the growth of such a mind as that of Jesus, which must be sought only in the seed of the immortal plant itself, it is by no means inconsistent with the highest ideas that can be entertained of the divinity of his nature, to suppose a progression in the development of his humanity. External influences must to a certain extent modify the character of every man. We are told, accordingly, that "he *grew* in *wisdom*" as well as "stature." And the commanding situation and romantic beauty of the city of his dwelling, the instructions of his mother, intercourse with the heathen, which, from the proximity of Nazareth to Galilee of the Gentiles, must have been frequent, may have proved among the subordinate aids for awakening that sense of the loveliness and majesty of external nature to which we find so many references in his discourses, and that susceptibility of every tender emotion which his whole history manifested, and that enlarged philanthropy which looked beyond the distinctions of Jew and Gentile, of sect and class, of rank and station, and considered the whole human race as members of one great family, as children of the same heavenly parent. Such influences, however, are matter of conjecture rather than of positive knowledge; for no reference is made to them by any of the Evangelists. The piety of his mother and of Joseph renders it certain that he would from infancy be made acquainted with the Old Testament Scriptures; and these not only contain the germ of all that is pure and elevating in religious sentiment, but also are, more than any other study, calculated to awaken the curiosity and stimulate the powers of the opening mind. His conversation and discourses everywhere show that he must have made a constant study of the sacred records. It appears that he never attended any rabbinical school, nor did he receive a learned education.[7]

From the time when he appeared disputing with the Jewish doctors in the temple, we have no direct information respecting him till his thirtieth year, when we find him among those who presented themselves to John upon the banks of the Jordan to be baptized. The intervening period was no doubt employed in maturing the plan for the arduous undertaking to which he was prompted by the stirrings of the Divinity within him. The consciousness of his high vocation, however, to a career that was to attract the notice of the world, did not interfere with the pious observance of his filial duties, or the laborious discharge of the common offices of his early situation.[8] The baptism of John served as a consecration to his new office. The heavens were opened, the Holy Spirit

[8] Luke, ii. 51; and Just. Mart. *ut sup.*

descended upon him, and a voice was heard from heaven declaring him to be the Son of God, and claiming for him the attention of mankind. Immediately after his initiation, he was impelled to retire into the solitudes of a wilderness, with a view, probably, of meditating on the work before him; and, by fasting and prayer, after the example of former prophets, to prepare himself for his great undertaking. A higher purpose was also accomplished during this retirement, an opportunity being afforded him for proving the purity and sinlessness of his nature, and establishing his fitness for the office upon which he had entered, by baffling the temptations of Satan.

After this mysterious conflict, Jesus returned to Bethabara, a place near to that part of the river Jordan over which the Israelites had passed under Joshua. It was here that disciples first began to gather around him; and few passages in history are more interesting than that[1] which tells of the individuals who first attached themselves to his cause; of their curiosity, their doubts, their conferences with him, the influence he gained over their minds, and their eagerness to communicate to others the wondrous tidings, that they had found the promised Messias in the person of Jesus of Nazareth. The first two individuals who joined themselves to him were disciples of John the Baptist, who pointed out Jesus when walking at a little distance, as the "Lamb of God who taketh away the sins of the world." Upon this they introduced themselves to his notice, and on his invitation accompanied him to the house where he lodged. What took place at this memorable interview, or how a solitary and almost unknown stranger attached to his cause the first two disciples, we are not informed; whether by some token of supernatural knowledge or power, or by the natural influence of a superior mind; the conviction was produced; and with it was imparted the spirit, which was at the foundation of the indefinite extension of the new cause, viz. the desire of imparting their own impressions of the new doctrines to others. One of the two individuals was Andrew, brother of Simon, who afterwards became so eminent in the primitive history of Christianity. "Andrew first findeth his own brother, and saith, we have found the Messias; and *he brought him to Jesus*." These three were the converts of the first day; and in a short time, without any advantages of birth or station, or human learning, without the aid of powerful relations or influential patrons, he had a considerable number of attached followers, who listened to his teaching, and accompanied him from place to place. At the feast of the Passover, along with the rest of his countrymen, Jesus went up to Jerusalem, where he increased the number of his disciples by his doctrines and miracles. He seems to have continued in the land of Judea about six or seven months; when the success of his preaching, exciting the attention and envy of the Scribes and Pharisees, led him to withdraw into Galilee, where the power of the Jewish Sanhedrim was less to be dreaded. In passing through Samaria, where the political circumstances of the inhabitants freed them from some of the prejudices of the Jews[2] respecting the character of the Messias, he first openly and publicly proclaimed the great truth, that all distinctions of Jews and Gentiles and Samaritans were to be at an end; and that, without reference to time or place, or outward ceremony, the Deity was to be worshipped in purity of spirit, and in faith on the promised Messias.[3] He then visited the whole of Galilee, everywhere accompanying the instruction he gave, in synagogues, or in private houses, or in the open fields, with miraculous proofs of his divine character and commission. In Nazareth he was first subjected to personal violence, his townsmen taking offence at his lowly origin. To avoid their malice, he passed on to Capernaum, which henceforth became the place of his general residence, and from which, as from a centre, he visited the whole surrounding country. The first year of his ministry seems to have been attended with almost universal success. He met with no outward obstruction in his work, except in Nazareth; his approach was everywhere welcomed, and increasing multitudes followed him in his progress.

During the second year of his ministry, his followers became so numerous that he chose twelve persons who might assist him in his work, and be prepared to propagate his religion when he should leave the world. These he named Apostles, an appellation which was appropriated at that time among the Jews to certain public officers who were the ministers of the high priests, and who were occasionally despatched on missions of importance to foreign parts.[4] The number twelve had probably a reference to the twelve tribes, as the seventy whom he afterwards chose might be from the number of the Jewish Sanhedrim. The increasing success of Jesus raised up against him a host of enemies, and from this time he was continually subjected to the cavils of the Sadducees, and still more of the Scribes and Pharisees, whose objections were of such a nature as might be expected from unprincipled and hypocritical men, who witnessed with jealousy any proceeding likely to diminish their influence among the people, and who were inflamed with resentment at the exposure which was made of their true character.

It has already been observed that Galilee was the chief scene of our Saviour's ministerial labours. He did not, however, confine himself wholly to that province, but occasionally visited other parts. We find him at one time on the coasts of Tyre and Sidon; at another beyond Jordan; and at the passover he uniformly went up to Jerusalem. As the Evangelists do not relate events in chronological order, we are without any precise information as to the exact degree of success that from this period attended his labours; it seems probable that his followers continued to increase, and that a deep and general impression was made upon the public mind. His proceedings at last excited the attention of all classes in Judea. Herod Antipas was haunted with the idea that he must be John the Baptist restored to life, and was desirous to have a personal interview with him; and there is not wanting reason to suppose that he received the homage of princes more remote. The eyes of the chief men of Judea were now upon him. The subject of his miracles was discussed in the Sanhedrim, and frequent attempts were made to seize and bring him before the council, though without any settled purpose, perhaps, how they were to proceed against him. At last, after the restoration of Lazarus to life, which led to the conversion of a multitude of the Jews, a meeting of the Pharisaic party was held, when it was finally determined that he should be put to death. The result is well known. In the dead of the night he was surprised in the midst of his secret devotions, hurried before the Sanhedrim, and, after the mockery of a trial, in which even his judge acknowledged his entire innocence, he was adjudged to suffer death. He was then carried to the usual place of execution, on a small hill named Calvary, on the west of Jerusalem, a little without the walls,

[3] Our information as to the first year of our Saviour's ministry is derived almost exclusively from John. The other Evangelists confine themselves to his preaching in Galilee, with the exception of what took place at Jerusalem immediately preceding the crucifixion.

[4] Mosheim *De Rebus Christianis*, &c. i. 6.

and there he was crucified. This dreadful scene was accompanied with signs and wonders which proclaimed the dignity of the sufferer. A supernatural darkness overspread the land of Judea, "and behold the veil of the temple was rent in twain, and the earth did quake, and the rocks rent, and the graves were opened." After his death his body was taken down from the cross, and laid in a tomb hewn out of a rock, after the manner of the Jewish sepulchres. Every precaution was used to prevent the removal of the body by the disciples. A great stone was rolled upon the door of the tomb, and a watch of Roman soldiers, consisting of sixty men, was appointed to guard it. This was on our Friday. The following day was the Jewish Sabbath; the stone remained in its place fixed and secure, and the soldiers continued their watch undisturbed. But on the morning of the third day, amidst a display of supernatural agency that mocked the precautions of the Jewish rulers, Jesus arose from the dead. After this he continued some time on earth, affording the most indubitable evidence of his identity, and of the reality of his resurrection from the dead, and instructing his disciples in the nature of the doctrine they were to teach mankind. At last, at the end of forty days, he led forth his disciples to Bethany, and there, while giving them his blessing, "he was parted from them, and carried up into heaven."[1]

The year of our Saviour's death cannot be exactly ascertained. Two extreme points, however, can be mentioned, within which that event must have taken place. The one is the fifteenth year of the reign of Tiberius,[2] in which John the Baptist began his ministry, and the other, the year in which that emperor died, when Pilate had left the province of Judea. As Jesus entered upon his ministry soon after the public appearance of John,[3] it would bring us to a near approximation to the date sought for, could we say how many passovers were celebrated by our Saviour. Even this, however, cannot be determined with certainty. The most probable opinion seems that of those who fix the number at three, and this would bring us to A. U. 783. Irenæus states that Jesus was forty or fifty years of age when he was put to death;[4] but it is generally agreed upon that his opinion was founded, not on authentic records, but to suit a fanciful theory.[5] Most of the Christian fathers assign only a single year to the ministry of Christ, and fix his death in A. U. 782. Their conclusions are drawn from an erroneous view of Isaiah, lxi. 1, and Luke, iv. 19.[6]

We have little authentic information respecting the character or history of Jesus additional to what is contained in the New Testament. The name Chrestus is mentioned by Suetonius; but it has been disputed whether he referred to Jesus.[7] Tacitus alludes to the fact of his death, and speaks of him as the founder of the sect of the Christians.[8] The chief notices of him by the fathers have been embodied in the preceding narrative. There is a passage in Josephus,[9] where his life and character are referred to in the following terms: "At that time lived Jesus, a wise man [if he may be called a man], for he performed many wonderful works. He was a teacher of such men as received the truth with pleasure. He drew over to him many Jews and Gentiles. [This was the Christ.] And when Pilate, at the instigation of the chief men among us, had condemned him to the cross, they who before had conceived an affection for him did not cease to adhere to him [for on the third day he appeared to them alive again, the divine prophets having foretold these and many wonderful things concerning him]. And the sect of the Christians, so called from him, subsists to this time." This remarkable passage is referred to by Eusebius,[10] and its genuineness was never called in question from his time till the sixteenth century, when Gifanius and Osiander refused to receive it. Since that period it has afforded matter for much controversy among the learned. In favour of the genuineness of the passage, it has been argued, that we have the undisputed fact that it is found in all the copies of the works of Josephus from the time of Eusebius. It also exists in a Hebrew translation in the Vatican; and there is an Arabic version preserved by the Maronites of Mount Libanus. In addition to this external evidence, it is urged that the number of Christians in the time of Josephus was too great to admit of the supposition that he should pass them over altogether unnoticed, an improbability which is increased by the fact that he makes mention of John the Baptist,[11] and of the death of "James, the brother of Jesus, called the Christ."[12] On the other hand, it is certain that Josephus was not himself a Christian; and yet the passage, as it stands in his writings, involves the profession of belief in the divine mission of Jesus. It is farther to be remarked, that this testimony in favour of Christ is not quoted by any of the apologists of Christianity who preceded Eusebius; and in particular, Origen,[13] while he refers to the allusion made by Josephus to the death of James, and to his account of John the Baptist, passes over in silence the passage in question, though it would have afforded a more decisive answer had it been contained in the copies of the Jewish historian then in circulation. The arguments on both sides appear plausible, and the difficulties upon either supposition cannot perhaps be removed but by the conjecture, that Josephus did introduce into his work a notice of Jesus, though without admitting him to be the Messias, and that some over-zealous Christian about the time of Eusebius had inserted some additional clauses. This opinion is now generally gone into by the continental critics. Those parts which are usually looked upon as interpolations are marked within brackets in the preceding extract.

It was scarcely possible that the appearance of so remarkable a character as that of our Saviour should not have induced many individuals, from various motives, to commit an account of him to writing. Accordingly, it appears,[14] that from the earliest period many histories of his life were in circulation. The words of St Luke seem to imply that these narratives were defective or erroneous; but there is nothing to prevent us from supposing that some of them might be the productions of men of good intentions, though deficient in the talents or information requisite for so important an undertaking. It was otherwise, however, in succeeding times. After the four gospels had been written by the Evangelists, and had been generally received as of divine authority in the Christian church, heretics and others, who departed from the true faith, had recourse to the expedient of forging gospels, epistles, &c. under the name of some of the apostles, or that of our Lord himself, to which they might refer in support of their tenets. These works were frequently formed out of the genuine gospels, with such additions and omissions as the purposes of the

Jesus. writers required. There were not wanting members of the true church who followed the same practice, with the mistaken idea that the piety of the faithful might thus be promoted, or that an answer might be afforded to some of the objections of Jews and Heathens. In the second century, Irenæus[1] tells us that the Gnostics had an innumerable multitude of spurious and apocryphal books; and in the following age they were greatly increased. The greater part of these writings perished in the course of ages. Of such of them as remained, a collection was published by Fabricius, about the beginning of last century, in his *Codex Apocryphus Novi Testamenti.* A full account of them is given, with translations, in Jones' well-known work on the Canon. Several of them were republished in London some years ago, in a work entitled *The Apocryphal New Testament.*

That these works are not to be received as genuine, may be proved by their vast inferiority to the canonical gospels, and still more decidedly by the fact, that they were not recognised by the Fathers. In *The Gospel of our Saviour's Infancy*, there are some passages which are referred to by Eusebius, Athanasius, and Chrysostom, as containing some trifling particulars of true history connected with the life of Christ, but it is not ranked by them among the inspired writings. It is worthy of remark, that it was from this production, and from *The Gospel of the Birth of Mary*, and the *Protevangelion of St James*, that Mahommed derived all his knowledge of our Saviour's life. Indeed he does not seem to have been at all acquainted with the canonical gospels; and the legends of the East in general concerning our Lord are all from apocryphal sources.[2]

There is an account in Eusebius,[3] of a message having been sent by Agbarus, king of Edessa, who had heard of the miracles of Jesus, and who requested him to come and cure him of a malady with which he was afflicted. It is added, that our Saviour wrote to him a letter, in which he promised to send one of his disciples to heal him. A translation of this correspondence from the Syriac original, contained in the archives of the church of Edessa, is given by Eusebius. Additions were afterwards made to the story,—as that Thaddeus, one of the seventy, was deputed by Thomas, after the resurrection, to fulfil the promise of the Saviour; and Evagrius[4] mentions, that our Lord not only wrote a letter, but that he sent a handkerchief also, with his picture drawn upon it. There can be no doubt that the letters mentioned by Eusebius actually existed among the records of Edessa, and that they were seen by that historian. But, in addition to the external evidence from the letters themselves, the fact that they are taken notice of by no preceding Christian writer affords demonstration that they are forgeries, which owe their existence probably to the national vanity of some of the early Christians of Edessa. We are not informed that our Saviour ever committed anything to writing, and we may be assured that if he had, it would not have passed unnoticed by his first followers.

There is another statement contained in Eusebius, deserving of more attention. He mentions that Pontius Pilate, after the crucifixion of our Lord, wrote such an account of his character and miracles to the Emperor Tiberius, as induced that prince to propose to the senate that a place should be assigned to Jesus among the deities worshipped by the Romans, but that the senate opposed the wishes of the emperor. It was certainly the custom of the governors of provinces to write memoirs of the remarkable occurrences of the places where they presided; and there is nothing improbable in the idea that Pilate, who was convinced of the innocence of Christ, should send an account of him to Tiberius. It is certain also that Justin Martyr,[5] in his Apology for the Christians, presented to the Emperor Antoninus Pius, refers to the acts of Pilate, as containing an account of the circumstances connected with the crucifixion; and Tertullian,[6] towards the end of the century, appeals to the same records. Still, however, we conceive that the evidence for the existence of these acts is defective; and the proposal alluded to by Tiberius to the Roman senate, though mentioned by Tertullian, and repeated by writers who succeeded him, is irreconcilable with the character of Tiberius, and the state of the Roman empire at that period. At a later period, a spurious work, entitled *The Acts of Pilate*,[7] was circulated by the Jews, containing many slanders against Jesus; and it appears that acts of a contrary nature were fabricated by certain Christians, to do away the impression.[8]

From the time that the Jews returned from the Babylonian captivity, a belief in magic formed a borrowed part of the national character; and at an early period the natural expedient was resorted to by the enemies of Jesus, of disparaging his character, by representing him as a magician. It was believed among them that there was a mystic word which enabled those who had learned it to direct at will the current of events; and a foolish story was circulated as early as the second century,[9] respecting the means by which Jesus discovered and remembered this potent sign. Upon this fable a life of Jesus was ultimately constructed, entitled *Toldoth Jeschu.* The substance of this abominable fabrication is, that Jesus was born in adultery, the particulars of which are detailed with revolting minuteness; that he contrived to steal the sacred word, by pronouncing which he performed miracles at will, healed the sick, opened the eyes of the blind, raised the dead; by means of such works he gained over many converts, and would have been still more successful had not another Jew disabused the minds of his countrymen by learning the same word, and disclosing to the people how the same miracles could be performed. The work terminates with an account of the death of Jesus, and of his body being stolen away by his disciples. It was published, with a Latin translation and learned notes, by Wagenseil, in his *Tela Ignea Satanæ, h. e. Arcani et horribiles Judæorum adversus Christum Deum et Christianum religionem libri* ΑΝΕΚΔΟΤΟΙ, 1681. It can scarcely be believed that the more learned among the Jews gave credit to its mendacious absurdities; though they long encouraged its circulation, to inspire their brethren with a deeper contempt for Christianity and its followers.

The determination of the questions relative to the person and character and history of Jesus involves all the essential particulars connected with the *evidences* and *doctrines* of the Christian faith. But in an article like the present, we cannot enter fully upon the consideration of any of these important subjects. We shall merely offer a few remarks upon such particulars as depend upon elements of a historical nature, leaving the discussion of matters of doctrine for other departments of this work.

The existence of such a person as Jesus Christ has scarcely ever been seriously denied; and the general tenor of the narrative of the Evangelists, with the omission of the miraculous parts, has been received as substantially correct by many who refuse to acknowledge the truth of our religion. The evidences for the genuineness and authenticity of the four Gospels will be stated under the proper

heads, from which it will appear that no history whatever is supported by stronger external proof; and that were it not from internal grounds as to the nature of the facts recorded, and the consequences which flow from them, the truth of the narrative would never have been called in question. Even the miracles were admitted by the earliest opponents of Christianity, Celsus, Philostratus, and Hierocles. These individuals did not deny the reality of the works performed by Jesus; they only, upon internal evidence, objected to the idea that a person in circumstances so lowly should be supposed to be divine, or explained away the supernatural appearances by the supposition of the exercise of magical arts,[1] or maintained that the few miracles which were performed did not warrant the idea of a divine character.[2]

Different ground has been taken up by infidels in modern times, who, while they have been constrained to admit the truth of the general statements of the Evangelists, have rejected altogether the supernatural machinery. In setting aside the miraculous part of the gospel history, the chief difficulty has been found in giving a consistent view of the character of Jesus. If the miracles performed by Christ were not real, the conclusion seems irresistible that he must have been either a deliberate impostor, or a self-deceived enthusiast. By some writers, accordingly, Jesus has been held up to ridicule and contempt, as exhibiting many weaknesses, and even vices—as a pretended miracle-worker and false prophet. Several of the deistical writers of our own country took up this position, and were followed by Voltaire and other French authors. The anti-Christian views of Voltaire were adopted by Frederick the Great,[3] whose example and encouragement gave rise to the spirit which has unfortunately led so many of the theologians of Germany to exclude from Christianity every trace of supernatural agency.

The notices of the English deists of the last century, respecting the miracles and character of Jesus, in many instances at least, were little more than incidental, and formed merely a part of their general argument against the truth of our religion. In Germany the work has been more systematically pursued. With the characteristic industry of that learned people, the writings of the Evangelists have been considered in every possible form. Different theories have been framed as to the secret views of Jesus, as to the real causes of his success, and as to the true character of the alleged miracles which were performed. Voltaire, after our English authors, had endeavoured to account for the exalted morality taught by Jesus, by supposing that it was borrowed from the self-denying tenets of the sect of the Essenes.[4] The idea was followed out by various German authors; while the lofty theology of the Alexandrian Platonists, and the liberal spirit of Sadduceism, were referred to by others as sufficient to originate in an enthusiastic mind the system taught by Jesus. Some, like Edelmann, while they have not disputed that a virtuous Jew named Jesus actually existed, have refused to acknowledge the genuineness and authenticity of the Gospels. Reimarus, in a posthumous tract[5] on the object of Jesus and his disciples, while he acknowledges the excellence of the morals, and even of the doctrines, of the Gospel, accuses Jesus of not observing the rules which he prescribed, and of making use of his system as a means for promoting his political views; and while he does justice to many of the high qualities of Jesus, he represents him, upon the whole, as actuated by ambition, and as aiming at the establishment of his own power under the character of the triumphant conqueror to whom the Jews looked forward in their promised Messias. His arguments are chiefly founded upon the acknowledged ideas of the Jewish people respecting the Messias, upon the caution exhibited by Jesus in arrogating that character, and upon his entering Jerusalem in royal state, when he conceived that his cause was sufficiently advanced to insure his success; while the grief he exhibited in the garden of Gethsemane, and his exclamation on the cross, "My God, my God, why hast thou forsaken me?" are considered as tokens of his disappointed hopes. This view has been taken by other writers, with various minor modifications, and with different degrees of learning and presumption. Others have represented Jesus as the dupe of his own imagination,—as one who, by the dreams of a fond mother, and the workings of an unrestrained fancy, was led to believe himself to be the Messias; and who, partly by his superior knowledge of the occult qualities of matter, and partly by the sympathetic influence of a highly-wrought enthusiasm, favoured occasionally by accidental circumstances, performed many works that seemed to exceed the limits of natural causes, which were afterwards exaggerated into real miracles. Another class of the neologian school describe Christ as a pure and exalted character, who was animated with the desire of raising the condition of his degraded countrymen, and of promoting the general interests of humanity; and who, in the lowly situation in which he was placed, found no other means of accomplishing this end but by personating the character of the Jewish Messias. As the Jews expected miracles to be performed by their long-looked-for Saviour, Jesus accommodated himself to their views in this respect. According to this class of writers, he is supposed sometimes to have availed himself of fortunate contingencies, representing the restoration from a faint as a resurrection from the dead, as in the case of the daughter of Jairus, and of Lazarus, and sometimes to have succeeded, perhaps beyond his own expectations, by the aids of animal magnetism.[6] His appearance to his disciples after his burial has

[3] Frederick, while he treated with contempt the doctrines of the Gospel, acknowledged the excellence of its morality, which he considered (it is unnecessary to remark how erroneously) as essentially the same with that of the Stoics.

[4] *Dict. Phil.* art. *Essenes.* The untenableness of the theory had long before been well exposed by Prideaux, *Connections*, vol. ii. p. 284.

[5] This tract was published in 1788, by the celebrated Lessing, among his "Wolfenbüttel Fragments by an anonymous person." It is entitled *Fragment von dem Zwecke Jesu und seiner junger.* It is now universally ascribed to Reimarus, well known as an able critic, and the author of a work on natural religion. He was born at Hamburg in 1694, and died in 1765. He published nothing respecting his views as to the subject of revealed religion during his life, but he left various manuscripts of an anti-christian character, some of which falling into the hands of Lessing, who at that time had the superintendence of the ducal library at Wolfenbüttel, were published by him in the *Beiträge zur Geschichte und Literatur, aus den Schätzen der Hezoglichen Bibliothek zu Wolfenbüttel.* They excited great attention; and, more perhaps than any other work, led to the neologian spirit that has since so much prevailed in Germany. Various answers were called forth. Of these, by far the ablest was that by Reinhard, a celebrated German preacher, in a work entitled *Versuch über den Plan den der Stifter der Christ. religion zum besten der Menschen entwarf.* The main object of the author is to show that the mere plan for effecting the happiness of the species; a plan which he purposed to carry into effect, not by violence or force of arms (in opposition to the theory of Reimarus), nor by the influence of a secret society (in opposition to the wild imagination of Bahrdt), but by means of moral suasion alone,—a plan which no great man of antiquity had ever conceived, and which entered into no other religious system; proves Jesus to have been a messenger sent by God. This work by Reinhard is one of the most valuable contributions to the evidences of the truth of Christianity. It has been translated into French; and a translation of it into English has been published in America, though it seems little known in this country.

[6] A list of the writers who hold these opinions is given in Winer's *Biblishes Realwörterbuch*, s. 671.

been also explained away, as if it had been the result of natural causes; it being argued that the suspension from the cross for a few hours was insufficient to occasion death, though in a worn-out frame it might occasion a temporary swoon, from which he might be restored by the myrrh and aloes and odoriferous substances which his disciples brought to embalm him.[1]
